(WHEN THIS RECOMMENDED PRACTICE IS FINALIZED, IT WILL CONTAIN THE FOLLOWING STATEMENT OF AUTHORITY:)

This document has been approved for publication by the Management Council of the Consultative Committee for Space Data Systems (CCSDS) and represents the consensus technical agreement of the participating CCSDS Member Agencies. The procedure for review and authorization of CCSDS Recommendations is detailed in the Procedures Manual for the Consultative Committee for Space Data Systems, and the record of Agency participation in the authorization of this document can be obtained from the CCSDS Secretariat at the address below.

This Recommended Practice is published and maintained by:

CCSDS Secretariat
Program Integration Division (Code MT)
National Aeronautics and Space Administration
Washington, DC  20546, USA
STATEMENT OF INTENT

(WHEN THIS RECOMMENDED PRACTICE IS FINALIZED, IT WILL CONTAIN THE FOLLOWING STATEMENT OF INTENT:)

The Consultative Committee for Space Data Systems (CCSDS) is an organization officially established by the management of member space Agencies. The Committee meets periodically to address data systems problems that are common to all participants, and to formulate sound technical solutions to these problems. Inasmuch as participation in the CCSDS is completely voluntary, the results of Committee actions are termed Recommendations and are not considered binding on any Agency.

This Recommended Practice is issued by, and represents the consensus of, the CCSDS Plenary body. Agency endorsement of this Recommended Practice is entirely voluntary. Endorsement, however, indicates the following understandings:

- Whenever an Agency establishes a CCSDS-related standard, this standard will be in accord with the relevant Recommendation. Establishing such a standard does not preclude other provisions which an Agency may develop.

- Whenever an Agency establishes a CCSDS-related standard, the Agency will provide other CCSDS member Agencies with the following information:
  -- The standard itself.
  -- The anticipated date of initial operational capability.
  -- The anticipated duration of operational service.

- Specific service arrangements shall be made via memoranda of agreement. Neither this Recommended Practice nor any ensuing standard is a substitute for a memorandum of agreement.

No later than five years from its date of issuance, this Recommended Practice will be reviewed by the CCSDS to determine whether it should: (1) remain in effect without change; (2) be changed to reflect the impact of new technologies, new requirements, or new directions; or, (3) be retired or canceled.

In those instances when a new version of a Recommendation is issued, existing CCSDS-related Agency standards and implementations are not negated or deemed to be non-CCSDS compatible. It is the responsibility of each Agency to determine when such standards or implementations are to be modified. Each Agency is, however, strongly encouraged to direct planning for its new standards and implementations towards the later version of the Recommended Practice.
FOREWORD

(WHEN THIS RECOMMENDED PRACTICE IS FINALIZED, IT WILL CONTAIN THE FOLLOWING FOREWORD:)

This document is a technical Recommended Practice for use in developing ground systems for space missions and has been prepared by the Consultative Committee for Space Data Systems (CCSDS). The Application Program Interface described herein is intended for missions that are cross-supported between Agencies of the CCSDS.

This Recommended Practice specifies service type specific extensions of the Space Link Extension Application Program Interface for Transfer Services specified by CCSDS (reference [6]). It allows implementing organizations within each Agency to proceed with the development of compatible, derived Standards for the ground systems that are within their cognizance. Derived Agency Standards may implement only a subset of the optional features allowed by the Recommended Practice and may incorporate features not addressed by the Recommended Practice.

Through the process of normal evolution, it is expected that expansion, deletion or modification to this document may occur. This Recommended Practice is therefore subject to CCSDS document management and change control procedures, as defined in the Procedures Manual for the Consultative Committee for Space Data Systems. Current versions of CCSDS documents are maintained at the CCSDS Web site:

http://www.ccsds.org/

Questions relating to the contents or status of this document should be addressed to the CCSDS Secretariat at the address indicated on page i.
At time of publication, the active Member and Observer Agencies of the CCSDS were:

**Member Agencies**

- Agenzia Spaziale Italiana (ASI)/Italy.
- British National Space Centre (BNSC)/United Kingdom.
- Canadian Space Agency (CSA)/Canada.
- Centre National d’Etudes Spatiales (CNES)/France.
- Deutsches Zentrum für Luft- und Raumfahrt e.V. (DLR)/Germany.
- European Space Agency (ESA)/Europe.
- Instituto Nacional de Pesquisas Espaciais (INPE)/Brazil.
- National Aeronautics and Space Administration (NASA)/USA.
- National Space Development Agency of Japan (NASDA)/Japan.
- Russian Space Agency (RSA)/Russian Federation.

**Observer Agencies**

- Austrian Space Agency (ASA)/Austria.
- Centro Tecnico Aerospacial (CTA)/Brazil.
- Chinese Academy of Space Technology (CAST)/China.
- Commonwealth Scientific and Industrial Research Organization (CSIRO)/Australia.
- Communications Research Laboratory (CRL)/Japan.
- Danish Space Research Institute (DSRI)/Denmark.
- European Organization for the Exploitation of Meteorological Satellites (EUMETSAT)/Europe.
- European Telecommunications Satellite Organization (EUTELSAT)/Europe.

- Ministry of Communications (MOC)/Israel.
- National Oceanic & Atmospheric Administration (NOAA)/USA.
- National Space Program Office (NSPO)/Taipei.
- Swedish Space Corporation (SSC)/Sweden.
- United States Geological Survey (USGS)/USA.
PREFACE

This document is a draft CCSDS Recommended Practice. Its draft status indicates that the CCSDS believes the document to be technically mature and has released it for formal review by appropriate technical organizations. As such, its technical contents are not stable, and several iterations of it may occur in response to comments received during the review process.

Implementers are cautioned not to fabricate any final equipment in accordance with this document’s technical content.

1 INTRODUCTION

1.1 PURPOSE

The Recommended Practice ‘Application Program Interface for Transfer Services – Core Specification’ (reference [7]) specifies a C++ API for CCSDS Space Link Extension Transfer Services. The API is intended for use by application programs implementing SLE transfer services.

Reference [7] defines the architecture of the API and the functionality that is independent of specific SLE service types.

The purpose of this document is to specify extensions to the API needed for support of the Forward Space Packet Service defined in reference [5].

1.2 SCOPE

This specification defines extensions to the SLE API in terms of:

a) the FSP specific functionality provided by API components;

b) the FSP specific interfaces provided by API components; and

c) the externally visible behavior associated with the FSP interfaces exported by the components.

It does not specify:

a) individual implementations or products;

b) the internal design of the components; and

c) the technology used for communications.

This Recommended Practice only defines interfaces and behavior that must be provided by implementations supporting the Forward Space Packet service in addition to the specification in reference [7].

1.3 APPLICABILITY

The FSP Application Program Interface specified in this document supports version 1 of the FSP service, as specified in reference [5].

1.4 RATIONALE

This Recommended Practice specifies the mapping of the Forward Space Packet service specification to specific functions and parameters of the SLE API. It also specifies the distribution of responsibility for specific functions between SLE API software and application software.
The goal of this Recommended Practice is to create a standard for interoperability between:

a) application software using the SLE API and SLE API software implementing the SLE API; and

b) SLE user and SLE provider applications communicating with each other using the SLE API on both.

This interoperability standard also allows exchangeability of different products implementing the SLE API, as long as they adhere to the interface specification of this Recommended Practice.

1.5 DOCUMENT STRUCTURE

1.5.1 ORGANIZATION

This document is organized as follows:

- Section 1 provides purpose and scope of this Recommended Practice, identifies conventions, and lists definitions and references used throughout the document;
- Section 2 describes the extension of the API model defined in reference [7] to include support for the FSP service;
- Section 3 contains detailed specifications for the API components and for applications using the API;
- Annex A provides a formal specification of the API interfaces and data types specific to the FSP service;
- Annex B lists all acronyms used within this document;
- Annex C lists informative references.

1.5.2 SLE SERVICE DOCUMENTATION TREE

The SLE suite of Recommendations is based on the cross support model defined in the SLE Reference Model (reference [4]). The services defined by the reference model constitute one of the three types of Cross Support Services:

a) Part 1: SLE Services;

b) Part 2: Ground Domain Services; and

c) Part 3: Ground Communications Services.

The SLE services are further divided into SLE service management and SLE transfer services.
The basic organization of the SLE services and SLE documentation is shown in figure 1-1. The various documents are described in the following paragraphs.

**Figure 1-1: SLE Services and SLE API Documentation**

a) *Cross Support Reference Model—Part 1: Space Link Extension Services*; a Recommendation that defines the framework and terminology for the specification of SLE services.

b) *Cross Support Concept—Part 1: Space Link Extension Services*; a Report introducing the concepts of cross support and the SLE services.

c) *Space Link Extension Services—Executive Summary*; an Administrative Report providing an overview of Space Link Extension (SLE) Services. It is designed to assist readers with their review of existing and future SLE documentation.

d) *Forward SLE Service Specifications*; a set of Recommendations that provide specifications of all forward link SLE services.
e) Return SLE Service Specifications; a set of Recommendations that provide specifications of all return link SLE services.

f) Internet Protocol for Transfer Services; a Recommendation providing the specification of the wire protocol used for SLE transfer services.

g) SLE Service Management Specifications; a set of Recommendations that establish the basis of SLE service management.

h) Application Program Interface for Transfer Services—Core Specification; a Recommended Practice document specifying the generic part of the API for SLE transfer services.

i) Application Program Interface for Transfer Services—Summary of Concept and Rationale; a Report describing the concept and rationale for specification and implementation of a Application Program Interface for SLE Transfer Services.

j) Application Program Interface for Return Services; a set of Recommended Practice documents specifying the service-type specific extensions of the API for return link SLE services.

k) Application Program Interface for Forward Services; a set of Recommended Practice documents specifying the service-type specific extensions of the API for forward link SLE services.

l) Application Program Interface for Transfer Services—Application Programmer's Guide; a Report containing guidance material and software source code examples for software developers using the API.

1.6 DEFINITIONS, NOMENCLATURE, AND CONVENTIONS

1.6.1 DEFINITIONS

1.6.1.1 Definitions from TC Space Data Link Protocol

This Recommended Practice makes use of the following terms defined in reference [3]:

a) AD, BD, BC;

b) Command Link Control Word (CLCW);

c) Frame Operation Procedure (FOP);

d) Multiplexer Access Point (MAP);

e) Virtual Channel (VC).

1.6.1.2 Definitions from SLE Reference Model

This Recommended Practice makes use of the following terms defined in reference [4]:
1.6.1.3 Definitions from FSP Service

This Recommended Practice makes use of the following terms defined in reference [5]:

a) association;
b) communications service;
c) confirmed operation;
d) invocation;
e) parameter;
f) performance;
g) port identifier;
h) return;
i) service instance provision period;
j) unconfirmed operation.

1.6.1.4 Definitions from ASN.1 Specification

This Recommended Practice makes use of the following terms defined in reference [8]:

a) Object Identifier;
b) Octet String.

1.6.1.5 Definitions from UML Specification

This Recommended Practice makes use of the following terms defined in reference [C7]:

a) Attribute;
b) Base Class;

c) Class;

d) Data Type;

e) Interface;

f) Method.

1.6.1.6 Definitions from API Core Specification

This Recommended Practice makes use of the following terms defined in reference [6]:

a) Application Program Interface;

b) Component.

1.6.2 NOMENCLATURE

The following conventions apply throughout this Recommended Practice:

a) the words ‘shall’ and ‘must’ imply a binding and verifiable specification;

b) the word ‘should’ implies an optional, but desirable, specification;

c) the word ‘may’ implies an optional specification;

d) the words ‘is’, ‘are’, and ‘will’ imply statements of fact.

1.6.3 CONVENTIONS

This document applies the conventions defined in reference [6].

The model extensions in section 2 are presented using the Unified Modelling Language (UML) and applying the conventions defined in reference [6].

The FSP specific specifications for API components in section 3 are presented using the conventions specified in reference [6].

The FSP specific interfaces in annex A are specified using the conventions defined in reference [6].
1.7 REFERENCES

The following documents contain provisions, which through reference in this text, constitute provisions of this document. At the time of publication, the editions indicated were valid. All documents are subject to revision, and users of this document are encouraged to investigate the possibility of applying the most recent editions of the documents indicated below. The CCSDS Secretariat maintains a register of currently valid CCSDS Reports and Recommendations.

NOTE – A list of informative references is provided in annex C.

2 OVERVIEW

2.1 INTRODUCTION

This section describes the extension of the SLE API model in reference [7] for support of the FSP service. Extensions are needed for the API components API Service Element and SLE Operations.

In addition to the extensions defined in this chapter, the component API Proxy must support encoding and decoding of FSP specific protocol data units.

2.2 PACKAGE FSP SERVICE INSTANCES

2.2.1 OVERVIEW

The FSP extensions to the component API Service Element are defined by the package FSP Service Instances. Figure 2-1 provides an overview of this package. The diagram includes classes from the package API Service Element specified in reference [7], which provide applicable specifications for the FSP service.

The package adds two service instance classes:

a) FSP SI User, supporting the service user role; and
b) FSP SI Provider, supporting service provider role.

These classes correspond to the placeholder classes I<SRV>_SI User and I<SRV>_SI Provider defined in reference [7].

Both classes are able to handle the specific FSP operations.

For the class FSP SI User, this is the only extension of the base class SI User.

The class FSP SI Provider adds three new interfaces:

a) IFSP_SIAadmin by which the application can set FSP specific configuration parameters;
b) IFSP_FOPMonitor by which the application can initialise and update parameters related to the FOP machine; and
c) IFSP_SIUpdate by which the application must update dynamic status information, required for generation of status reports.

These interfaces correspond to the placeholder interfaces I<SRV>_SIAadmin and I<SRV>_SIUpdate defined in reference [7]. For the FSP service, the conceptual interface I<SRV>_SIAadmin is split into the two interfaces IFSP_SIAadmin and IFSP_FOPMonitor because of the large number of parameters that must be handled.
FSP specific service parameters are defined by the internal classes FSP Configuration and FOP Monitor. The class FSP Status Information defines dynamic status parameters maintained by the service instance. In addition, the service instance maintains a set of parameters for the last packet for which processing started and for the last packet for which processing was successfully completed. These parameters are defined by the classes Packet Last Processed and Packet Last OK.

All specifications provided in this section refer to a single service instance. If more than one service instance is used, each service instance must be configured and updated independently.
2.2.2 COMPONENT CLASS FSP SI USER

The class defines a FSP service instance supporting the service user role. It ensures that SLE PDUs passed by the application and by the association are supported by the FSP service and handles the FSP operation objects defined in 2.3. It does not add further features to those provided by the base class SI User.

Figure 2-1: FSP Service Instances
2.2.3 COMPONENT CLASS FSP SI PROVIDER

The class defines a FSP service instance supporting the service provider role. It exports the interfaces IFSP_SIAdmin for configuration of the service instance after creation, IFSP_FOPMonitor for update of FOP parameters, and IFSP_SIUpdate for update of dynamic status parameters during operation.

2.2.3.1 Responsibilities

2.2.3.1.1 Service Specific Configuration

The service instance implements the interface IFSP_SIAdmin to set the FSP specific configuration parameters defined by the class FSP Configuration. The methods of this interface must be called after creation of the service instance. When all configuration parameters (including those set via the interface ISLE_SIAdmin and the interface IFSP_FOPMonitor) have been set, the method ISLE_SIAdmin::ConfigCompleted() must be called. This method verifies that all configuration parameter values are defined and are in the range defined in reference [5].

In addition, the interface IFSP_SIAdmin provides read access to the configuration parameters.

2.2.3.1.2 Initialization and Update of FOP Parameters

The service instance implements the interface IFSP_FOPMonitor for initialization and update of the parameters defined by the class FOP Monitor. The API service instance uses these parameters only to respond to GET-PARAMETER invocations. The application must initialise these parameters when configuring the service instance and update them whenever they change during the lifetime of the service instance.

Changes of the parameter values might occur due to directives invoked by a service user on the same or on a different service instance, due to events detected by the FOP machine, or due to management action. In order to ensure that the service instance always reports the correct parameter value, updates must be forwarded independent of the service instance state.

2.2.3.1.3 Update of Dynamic Status Parameters

The class implements the interface IFSP_SIUpdate to inform the service instance of specific events in the FSP production process. The methods of this interface update status parameters defined by the classes FSP Status Information, Packet Last Processed, and Packet Last OK. The events reported via IFSP_SIUpdate and the parameters updated via this interface are listed in table 2-1.

In order to ensure that the status information is always up to date the events listed in table 2-1 must be reported to the service instance during its complete lifetime, independent of the state of the service instance.
In addition, the class derives some of the parameters in FSP Status Information from FSP PDUs exchanged between the service user and the service provider. The methods used to update each of the parameters are defined in 3.1.4.13.

The interface `IFSP_SIUpdate` provides read access to all status parameters.
Table 2-1: Production Events Reported via the Interface IFSP_SIUpdate

NOTE – The notification type actually transmitted depends on the method arguments and partially or the value of the production status.

<table>

</tbody>
</table>
NOTES

1. If the transmission mode is sequence controlled.
2. If the transmission mode is expedited.
3. If the packet id last processed is contained in the affected packets list argument.
4. If no packets were affected, the list is empty.
5. Only needed in case of a transmission mode capability change.
6. Only needed in case of a negative result.
2.2.3.1.4 Generation of Notifications

If events reported via the interface IFSP_SIUpdate require that a FSP–ASYNC–NOTIFY invocation be sent to the service user, the class generates and transmits the invocation if that is requested by the application and if the state of the service instance is ‘active’ or ‘ready’. The notifications that are generated and transmitted by the class are listed in table 2-1. The application can opt not to use this feature, but to generate the notification itself and transmit it using the interface ISLE_ServiceInitiate.

2.2.3.1.5 Handling of the FSP–GET-PARAMETER Operation

The class responds autonomously to FSP–GET–PARAMETER invocations. It generates the appropriate FSP–GET–PARAMETER return using the parameters maintained by the classes FSP Configuration, FOP Monitor, and FSP Status Information.

2.2.3.1.6 Status Reporting

The class generates FSP–STATUS–REPORT invocations when required using the parameters maintained by the classes FSP Status Information, Packet Last Processed, and Packet Last OK.

2.2.3.1.7 Processing of FSP Protocol Data Units

The class ensures that SLE PDUs passed by the application and by the association are supported by the FSP service and handles the FSP operation objects defined in 2.3.

2.2.3.1.8 Processing of FSP–TRANSFER–DATA Invocations

For incoming FSP–TRANSFER–DATA invocations the class performs the checks defined in 3.1.5.1 in addition to those defined in reference [6].

In contrast to standard handling of confirmed operations, the service instance is allowed to pass the operation object to the application after setting the correct diagnostic if these checks fail. The application is expected to insert the next expected packet identification and the available buffer size into the operation object and pass it back to service instance via the interface ISLE_ServiceInitiate. The reasons for this specification are explained in 2.2.9.3.

2.2.3.1.9 Processing of FSP–THROW-EVENT invocations

In contrast to standard handling of confirmed operations, the service instance is allowed to pass the operation object to the application after setting the correct diagnostic if checks performed by the service element fail. The application is expected to insert the next expected event invocation identifier into the operation object and pass it back to service instance via the interface ISLE_ServiceInitiate. The reasons for this specification are explained in 2.2.9.3.
2.2.3.1.10 Processing of FSP–INVOKE-DIRECTIVE invocations

For incoming FSP–INVOKE-DIRECTIVE invocations the class verifies that the service instance has the capability to invoke directives in addition to the checks defined in reference [7].

In contrast to standard handling of confirmed operations, the service instance is allowed to pass the operation object to the application after setting the correct diagnostic if checks performed by the service element fail. The application is expected to insert the next expected directive invocation identifier into the operation object and pass it back to service instance via the interface ISLE_ServiceInitiate. The reasons for this specification are explained in 2.2.9.3.

2.2.4 INTERNAL CLASS FSP CONFIGURATION

The class defines the configuration parameters that can be set via the interface IFSP_SIAdmin. These parameters are defined by reference [5]. Table 2-2 describes how the service instance uses these parameters. The column labeled ‘Upd’ indicates whether an update of these parameters is allowed after the initial configuration has been completed. Table 2-2 only indicates which parameters must not be modified in order to ensure proper operation of the API. Updates allowed by the table might be inhibited because of other constraints.

2.2.5 INTERNAL CLASS FOP MONITOR

The class defines the FOP parameters that can be initialized and updated via the interface IFSP_FOPMonitor. These parameters are defined by reference [5]. Table 2-3 describes how the service element uses these parameters. The parameters 'map multiplexing scheme' and 'map multiplexing control' are assigned to this class because 'map multiplexing control' can be modified by a service user via a directive in the same way as FOP control parameters.

2.2.6 INTERNAL CLASS FSP STATUS INFORMATION

The class defines status parameters handled by the service instance. The parameters are defined by reference [5]. Table 2-4 describes how the service element updates each of the parameters and how it uses the parameters.

</tr>
<tr>
<td>directive-invocation-online</td>
<td>See Note</td>
<td>FSP-GET-PARAMETER</td>
</tr>
</tbody>
</table>

**NOTE** – The value of the parameter directive-invocation-online at the time the service instance is configured must be specified by the application if directive invocation is not enabled for the service instance. Subsequently, the API updates the parameter when the methods NoDirectiveCapability() and DirectiveCapabilityOnline() are invoked on the interface IFSP_SIUpdate. For service instances with invocation capability enabled, the parameter is initialised to ‘no’ and subsequently set to ‘yes’ when the user binds and to 'no' when the user unbinds or the association is aborted.

### 2.2.7 INTERNAL CLASS PACKET LAST PROCESSED

The class defines the parameters maintained by the service instance for the last packet for which processing started or was attempted. These parameters are defined in reference [5].

All parameters are set via methods in the interface IFSP_SIUpdate (see table 2-1) and are used in status reports and notifications.

### 2.2.8 INTERNAL CLASS PACKET LAST OK

The class defines the parameters maintained by the service instance for the last packet for which processing was completed. For BD packets completion implies that the packet was radiated. AD packets are considered complete when all segments of the packet have been acknowledged by a CLCW.

These parameters are defined in reference [5]. All parameters are set via methods in the interface IFSP_SIUpdate (see table 2-1) and are used in status reports and notifications.
2.2.9 FEATURES NOT HANDLED BY THE PROVIDER SIDE SERVICE INSTANCE

2.2.9.1 Introduction

As a general approach, this specification only states what the API is required to do. Features not identified in this specification cannot be expected from a conforming implementation. This section deviates from this approach by discussing features not provided by the API, with the intention to clarify the borderline between the application and the API Service Element.

In addition, this section outlines the rationale for the distribution of responsibilities between the application and the API Service Element in this specification.

2.2.9.2 Production Status

Reference [5] defines the parameter production status, which reflects the state of the FSP production engine. The value of the production status is not only included in status reports and notifications, but also determines whether invocations of the operations FSP–BIND and FSP–START can be accepted or not. The production status also has an impact on processing of FSP–TRANSFER–DATA operations, which is discussed in 2.2.9.4.

Table 2-5 lists the possible values of the production status and the required processing of BIND and START invocations.

<table>
<thead>
<tr>
<th>Production Status</th>
<th>BIND invocation</th>
<th>START invocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>halted</td>
<td>reject (out of service)</td>
<td>reject (out of service)</td>
</tr>
<tr>
<td>configured</td>
<td>accept</td>
<td>accept</td>
</tr>
<tr>
<td>operational</td>
<td>accept</td>
<td>accept</td>
</tr>
<tr>
<td>interrupted</td>
<td>accept</td>
<td>reject (unable to comply)</td>
</tr>
</tbody>
</table>

In a multi-threaded environment, the value of the production status can change concurrently with processing within the service element. That implies that the value can change after a PDU has been processed by the service element but before the same PDU is handled by the application. Because the service element cannot guarantee that the result of a test is still valid when the PDU reaches the application, this specification does not require that the service element check the production status.

This specification does not exclude that implementations of the service element check the production status and reject BIND or START invocations if required. If both the API and the application are single-threaded, the application could rely on such checks. However, applications cannot expect that other implementations provide the same service. Therefore,
applications wishing to maintain substitutability of API components should not rely on such behavior.

### 2.2.9.3 TRANSFER-DATA, INVOKE DIRECTIVE, and THROW-EVENT

For FSP–TRANSFER–DATA returns, reference [5] requires that the provider inserts the next expected packet identification and the available packet buffer size. For FSP-INVOKE-DIRECTIVE and FSP-THROW-EVENT returns, reference [5] requires that the provider inserts the next expected directive identification or event invocation identification, respectively. These parameters are available to the service element via the procedures described in 2.2.6. However, the following must be considered.

A service user is not required to wait for a FSP–TRANSFER–DATA return before transmitting the next FSP–TRANSFER–DATA invocation. Therefore, several FSP–TRANSFER–DATA invocations can be in transit. Depending on the implementation of the service element and of the provider application, FSP–TRANSFER–DATA invocations might be queued between the service element and the application. In such a case, the service element cannot know what values to insert for the next packet identification and the available buffer size when it needs to generate a FSP–TRANSFER–DATA return with a negative result. The same considerations apply to the FSP-INVOKE-DIRECTIVE and FSP–THROW–EVENT operations.

Therefore, this Recommended Practice defines a procedure for the operations FSP–TRANSFER–DATA, FSP-INVOKE-DIRECTIVE, and FSP–THROW–EVENT, which deviates from the standard approach described in reference [7]. When a check performed by the service element fails, the service element may set the appropriate diagnostic in the operation object and pass the operation object to the application. The application is expected to check the result of an invocation. If the result is negative, the application shall insert the next expected packet identification and the available buffer size, the next expected directive identification, or the next expected event invocation identification into the operation object and then pass it back to the service element using the method `InitiateOpReturn()` in the interface `ISLE_ServiceInitiate`.

This specification does not exclude that implementations generate a FSP–TRANSFER–DATA return, a FSP-INVOKE-DIRECTIVE return, or a FSP–THROW–EVENT return if it is possible to insert the correct values for the return parameters. An implementation can apply any of the following approaches:

a) an implementation can always pass invocations for which a check has failed to the application;

b) an implementation can prevent queuing of invocations by withholding an invocation until the previous invocation has been confirmed by the application. In that case, it can always generate the appropriate return when needed; or

c) an implementation can decide to pass invocations to the application on a case-by-case basis.
Applications wishing to maintain substitutability of API components should always expect to receive FSP–TRANSFER–DATA invocations, FSP-INVOKE-DIRECTIVE invocations, and FSP–THROW–EVENT invocations with a negative result from the service element.

2.2.9.4 Processing of TRANSFER-DATA Invocations

2.2.9.4.1 Blocked State of the Service Instance

When a packet cannot be processed because the production status becomes non-operational or because the latest production start time expired the service instance becomes blocked and further FSP–TRANSFER–DATA invocations must be rejected. In order to clear the situation, the service user must invoke a FSP–STOP operation followed by a FSP–START operation.

The event causing the blocked state of the service instance can depend on the production status, which can change concurrently with processing in the service element. In a multi-threaded environment, the service element cannot guarantee that a FSP–TRANSFER–DATA invocation that passed the test of the blocked state is still valid when it reaches the application. Therefore, this specification does not require the service element to perform that check.

This specification does not exclude that implementations check the blocked state of the service instance. If both the API and the application are single-threaded, the application could rely on such checks. However, applications cannot expect that other implementations provide the same service. Applications wishing to maintain substitutability of API components must not rely on such behavior.

2.2.9.4.2 Transmission Mode Capability

When an AD packet cannot be processed because the required transmission mode capability is not available the AD mode becomes blocked and further AD packets must be rejected. In order to clear the situation, the user must invoke an FSP-TRANSFER-DATA operation with the transmission mode 'sequence controlled and unblock AD'.

The transmission mode capability can change and the AD service can become blocked concurrently with processing in the service element. In a multi-threaded environment, the service element cannot guarantee that a FSP–TRANSFER–DATA invocation that passed the test of the AD blocked state is still acceptable when it reaches the application. Therefore, this specification does not require the service element to perform that check.

This specification does not exclude that implementations check whether the AD service is blocked. If both the API and the application are single-threaded, the application could rely on such checks. However, applications cannot expect that other implementations provide the same service. Applications wishing to maintain substitutability of API components must not rely on such behavior.
2.2.9.4.3 Checking of Time Parameters

FSP–TRANSFER–DATA invocations carry parameters that specify the earliest and latest production start times. Reference [5] requires the service provider to check that these times are not expired at the time the invocation reaches the provider. It cannot be excluded that such a time expires after the invocation has been processed by the service element, but before it reaches the application. Therefore, this specification does not require the service element to perform these checks. The service element is, however, required to verify that time periods are defined in a consistent manner.

This Recommended Practice does not exclude that implementations check times against current time. However, applications wishing to maintain substitutability of API components must not rely on such behavior.

2.2.9.4.4 APID, Packet Version, and Packet Type

Reference [5] requires that the FSP service provider verify that:

a) the APID of a packet matches one of the entries in the list of permitted APIDs;

b) the packet version is supported by CCSDS and the service instance; and

c) the packet type specifies telecommand.

For these checks it is necessary to inspect the packet delivered by the parameter 'data' in the TRANSFER-DATA operation. Because the SLE Application Program Interface generally handles space link data units as opaque data types, this specification does not require a service element to perform these checks.

This specification does not exclude that implementations check the APID, packet version, and packet type. However, applications wishing to maintain substitutability of API components must not rely on such behavior.

2.2.9.5 Production Time

Reference [5] defines a production period, i.e. the period in which the FSP production engine is able to process packets. This period must overlap with the scheduled provision period of the service instance but need not be the same. Reference [5] requires the service provider to check the validity of FSP–START invocations and FSP–TRANSFER–DATA invocations against the production period.

This specification does not require a service element to perform these checks, as they are related to service production and not to service provisioning.

2.3 PACKAGE FSP OPERATIONS

Figure 2-2 shows the operation object interfaces required for the FSP service. The package FSP Operations adds operation objects for the following FSP operations:
a) FSP–START;
b) FSP–TRANSFER–DATA;
c) FSP–ASYNC–NOTIFY;
d) FSP–STATUS–REPORT;
e) FSP–GET–PARAMETER;
f) FSP–THROW–EVENT;
g) FSP–INVOKE–DIRECTIVE.

For other operations the API uses the common operation objects defined in reference [7].

3 FSP SPECIFIC SPECIFICATIONS FOR API COMPONENTS

3.1 API SERVICE ELEMENT

3.1.1 SERVICE INSTANCE CREATION

3.1.1.1 The service element shall allow creation of service instances supporting the Forward Space Packet (FSP) service.

3.1.1.2 FSP service instances shall be provided to support the service provider role and the service user role.

NOTE – As specified by reference [7], a given implementation of the component API Service Element might support only the user role, only the provider role, or both roles.

3.1.2 SERVICE INSTANCE CONFIGURATION

3.1.2.1 The service element shall provide the interface $\text{IFSP\_SIAdmin}$ for configuration of a provider-side service instance after creation.

3.1.2.2 The interface $\text{IFSP\_SIAdmin}$ shall provide methods to set the following configuration parameters, which the service element uses to respond to GET-PARAMETER invocations received from the service user:

- a) apid-list;
- b) blocking-timeout-period;
- c) blocking-usage;
- d) directive-invocation-enabled;
- e) map-list;
- f) maximum-frame-length;
- g) maximum-packet-length;
- h) segment-header;
- i) vc-multiplexing-control;
- j) vc-multiplexing-scheme; and
- k) virtual-channel.

NOTE – These parameters are defined in reference [5] for the operation FSP-GET-PARAMETER.
3.1.2.3 The interface IFSP_SIAdmin shall provide a method to set the initial value of the parameter directive-invocation-online if the configuration parameter directive-invocation-enabled is set to 'no'.

NOTE – The parameter directive-invocation-online is defined in reference [5] for the operation FSP-GET-PARAMETER. Further processing of this parameter is described in 3.1.4.13.

3.1.2.4 The interface IFSP_SIAdmin shall provide methods to set the following parameters, which the service instance uses to initialize parameters of the status report:

a) the maximum size of the packet buffer shall be used to initialize the parameter packet-buffer-available;

b) the value of the production status at the time the service instance is configured.

NOTE – Further configuration parameters must be set using the interface ISLE_SIAdmin specified in reference [5] and the interface IFSP_FOPMonitor defined in 3.1.4.

3.1.2.5 All configuration parameters must be set before the method ConfigCompleted() of the interface ISLE_SIAdmin is called. If one of the parameters is omitted or the value of a parameter is not within the range specified by reference [5], the method ConfigCompleted() shall return an error.

NOTES

1 As defined in reference [7], the service element starts processing of the service instance only after successful configuration.

2 The range of specific parameter values might be further constrained by service management. The service element shall only check on the limits specified by reference [5].

3.1.2.6 Configuration parameters listed in 3.1.2.2 can be modified at any time during operation of the service instance. The service element shall always use the most recent value.

NOTE – Modification of these parameters during the scheduled provision period of the service instance might be inhibited by service management. Such constraints must be handled by the application.

3.1.2.7 Configuration parameters defined in 3.1.2.3 and 3.1.2.4 must not be modified after successful return of the method ConfigCompleted() defined in the interface ISLE_SIAdmin. The effect of an attempt to set these parameters after completion of the configuration is undefined.
3.1.2.8 The values of the configuration parameters identified in 3.1.2.2 shall remain unmodified following an FSP-UNBIND or FSP-PEER-ABORT operation and following a protocol-abort.

3.1.2.9 The interface IFSP_SIAdmin shall provide methods to retrieve the values of the configuration parameters. The values returned by these methods before configuration has been completed are undefined.

3.1.3 INITIALISATION AND UPDATE OF FOP PARAMETERS

3.1.3.1 The service element shall provide the interface IFSP_FOPMonitor for initialization and update of parameters related to the FOP machine in a provider side service instance.

3.1.3.2 The interface IFSP_FOPMonitor shall provide methods to set the following parameters, which the service element uses to respond to GET-PARAMETER invocations received from the service user:

   a) fop-sliding-window;
   b) timeout-type;
   c) timer-initial;
   d) transmission-limit;
   e) transmitter-frame-sequence-number;
   f) fop-state;
   g) map-multiplexing-control; and
   h) map-multiplexing-scheme.

NOTES

1 These parameters are defined in reference [5] for the operation FSP-GET-PARAMETER.

2 The parameters map-multiplexing-scheme and map-multiplexing-control are included in this interface because map-multiplexing-control can be modified by the service user via a directive in the same way as FOP control parameters.

3.1.3.3 Initial values for the parameters listed in 3.1.3.2 must be set before the method ConfigCompleted() of the interface ISLE_SIAdmin is called. If one of the parameters is omitted, or the value of a parameter is not within the range specified by reference [5], the method ConfigCompleted() shall return an error.
3.1.3.4 During the complete lifetime of the service instance the parameters listed in 3.1.3.2 must be updated via the interface IFSP_FOPMonitor, whenever their value changes.

NOTES

1 Changes might occur due to directives invoked by a service user on the same or on a different service instance, due to events detected by the FOP machine, or due to management action.

2 In order to ensure that the service instance always reports the correct parameter value, updates must be reported independent of the service instance state.

3.1.3.5 The interface IFSP_FOPMonitor shall provide methods to retrieve the values of the parameters. The values returned by these methods before configuration has been completed are undefined.

3.1.4 STATUS INFORMATION

3.1.4.1 Status Parameters

3.1.4.1.1 The service element shall maintain status parameters for every service instance and use them for generation of status reports, notifications, and for FSP–GET–PARAMETER returns.

NOTES

1 The parameters are defined in reference [5] for the operations FSP-ASYNC-NOTIFY, FSP-STATUS-REPORT, and FSP-GET-PARAMETER.

2 Handling of the parameter reporting-cycle defined for the FSP-GET-PARAMETER operation shall be specified in reference [7].

3.1.4.1.2 The service element shall update the following status parameters in the methods of the interface IFSP_SIUpdate described in 3.1.4.2

a) packet-identification-last-processed;
b) packet-status;
c) production-start-time;
d) packet-identification-last-OK;
e) production-stop-time;
f) production-status;
g) number-of-AD-packets-processed;
h) number-of-BD-packets-processed;

i) number-of-AD-packets-radiated;

j) number-of-BD-packets-radiated; and

k) number-of-AD-packets-acknowledged.

NOTE – The initial values of these parameters following configuration of the service instance are defined in A4.3.

3.1.4.1.3 The service element shall handle the parameter directive-invocation-online as defined by the following specifications:

NOTE – The parameter directive-invocation-online can be requested by an FSP-GET-PARAMETER invocation.

a) when the parameter directive-invocation-enabled is 'no', the initial value shall be set by configuration of the service instance. Subsequently the value shall be set to 'yes' when the method DirectiveCapabilityOnline() is invoked and it shall be set to 'no' when the method NoDirectiveCapability() is called on the interface ISLE_SIUpdate;

b) when the parameter directive-invocation-enabled is 'yes', the initial value shall be set to 'no'. Subsequently the value shall be set to 'yes' when the user binds and it shall be reset to 'no' when the user unbinds or when the association is aborted.

3.1.4.1.4 The service element shall handle the parameter expected-sldu-identification as defined by the following specifications:

NOTE – The parameter expected-sldu-identification can be requested by an FSP-GET-PARAMETER invocation.

a) the parameter shall be set to zero when the service instance is configured;

b) when the application transmits an FSP-START return with a positive result, the value shall be set to the value of the parameter first-packet-identification in the FSP-START invocation;

c) the value shall be copied from the parameter packet-identification in every FSP-TRANSFER-DATA return issued by the application.

3.1.4.1.5 The service element shall handle the parameter expected-directive-identification as defined by the following specifications:

NOTE – The parameter expected-directive-invocation-identifier can be requested by an FSP-GET-PARAMETER invocation.

a) the parameter shall be set to zero when the service instance is configured;
b) the value shall be copied from every FSP-INVOKE-DIRECTIVE return issued by the application.

3.1.4.1.6 The service element shall handle the parameter expected-event-invocation-identifier as defined by the following specifications:

NOTE – The parameter expected-event-invocation-identifier can be requested by an FSP-GET-PARAMETER invocation.

a) the parameter shall be set to zero when the service instance is configured;

b) the value shall be copied from every FSP-THROW-EVENT return issued by the application.

3.1.4.1.7 The service element shall handle the parameter packet-buffer-available as defined by the following specifications:

a) at configuration time, the value shall be copied from the configuration parameter maximum-packet-buffer, defined in 3.1.2.4.

b) when the application transmits an FSP-TRANSFER-DATA return the value shall be copied from the parameter set by the application;

c) the value shall be updated whenever passed as argument by one of the methods in the interface IFSP_SIUpdate;

d) when the application transmits an FSP-STOP return with a positive result, the value shall be copied from the configuration parameter maximum-packet-buffer;

e) when the application or the service element transmits an FSP-ASYNC-NOTIFY invocation with the parameter notification-type set to ‘buffer empty’, the value shall be copied from the configuration parameter maximum-packet-buffer;

NOTE – The service element shall transmit the notification when requested by the application via the interface IFSP_SIUpdate specified in 3.1.4.2.

f) following an FSP-PEER-ABORT operation and following protocol-abort, the value shall be copied from the configuration parameter maximum-packet-buffer.

3.1.4.1.8 The service element shall handle the parameter number-of-AD-packets-received as defined by the following specifications:

a) the parameter shall be set to zero when the service instance is configured;

b) the parameter shall be incremented whenever the application transmits an FSP-TRANSFER-DATA return with a positive result and the parameter transmission-mode was set to ‘sequence controlled’ in the invocation.
3.1.4.1.9 The service element shall handle the parameter number-of-BD-packets-received as follows:

a) the parameter shall be set to zero when the service instance is configured;

b) the parameter shall be incremented whenever the application transmits an FSP-TRANSFER-DATA return with a positive result and the parameter transmission-mode was set to ‘expedited’ in the invocation.

3.1.4.1.10 Except for the parameters packet-buffer-available and directive-invocation-online, status parameters defined in this Recommended Practice shall not be modified as result of FSP-UNBIND, FSP-PEER-ABORT, or protocol abort.

NOTE – The parameter directive-invocation-online shall be set to ‘no’ as result of an UNBIND operation or of an abort only when the directive invocation is enabled for the service instance. If directive invocation is not enabled, the parameter shall not be modified. It can, however, change in periods when the service instance is not bound.

3.1.4.1.11 The interface IFSP_SIUpdate shall provide methods to retrieve the values of all status parameters. The values returned by these methods shall be undefined before configuration has been completed.

3.1.4.2 Update of Status Information by the Application

3.1.4.2.1 The service element shall provide the interface IFSP_SIUpdate for a provider-side service instance. This interface shall be used by the application to inform the service element of specific events in the production process.

3.1.4.2.2 When methods of this interface are called, the service element shall:

a) update the status parameters according to the arguments passed with the method invocations;

b) generate and transmit the following notifications if requested by the application and if the state of the service instance is ‘ready’ or ‘active’:

1) ‘packet processing started’;
2) ‘packet radiated’;
3) ‘packet acknowledged’;
4) ‘sldu expired’;
5) ‘packet transmission mode mismatch’;
6) ‘transmission mode capability change’;
7) ‘buffer empty’;
8) ‘no invoke directive capability on this VC’;
9) ‘invoke directive capability on the VC established’;
10) ‘positive confirm response to directive’;
11) ‘negative confirm response to directive’;
12) ‘VC aborted’;
13) ‘production interrupted’;
14) ‘production halted’;
15) ‘production operational’;
16) ‘action list completed’;
17) ‘action list not completed’; and
18) ‘event condition evaluated to false’.

NOTE – The application may opt to generate and transmit the notifications itself using the interface ISLE_ServiceInitiate as for other PDUs.

3.1.4.2.3 The application must inform the service element of the events defined in 3.1.4.2.1 to 3.1.4.12.1 via the interface IFSP_SIUpdate during the complete lifetime of the service instance, independent of the state of the service instance.

NOTE – This applies regardless of whether the application opts or not opts to generate and transmit the notifications itself using the interface ISLE_ServiceInitiate as for other PDUs.

3.1.4.2.4 The application should invoke the methods of the interface IFSP_SIUpdate when one of the events defined in 3.1.4.13.1 and 3.1.4.14.1 occurs to generate the appropriate notification and send it to the service user.

NOTES

1 The methods described in 3.1.4.2.1 to 3.1.4.12.1 update status parameters maintained by the service instance. Status information must be updated in periods in which the service user is not connected such that it is up to date following a successful BIND operation. Failure to report one of the events defined in 3.1.4.2.1 to 3.1.4.12.1 can result in inconsistent status information.

2 Generation and transmission of notifications can be disabled by a method argument if this feature is not wanted.
3. The methods described in 3.1.4.13.1 and 3.1.4.14.1 do not affect status information maintained by the service instance. Therefore, an application generating and transmitting notifications itself does not need to call these methods.

3.1.4.3 Packet Processing Started

3.1.4.3.1 The application calls the method `PacketStarted()` of the interface `IFSP_SIUpdate` whenever processing of a packet started.

3.1.4.3.2 When calling the method `PacketStarted()` the application shall provide the following information using the method arguments:

- a) the identification and transmission mode of the packet for which processing started;
- b) the time at which processing started; and
- c) the available buffer size.

3.1.4.3.3 The method `PacketStarted()` shall:

- a) increment the parameter `number-of-AD-packets-processed` or `number-of-BD-packets-processed` depending on the transmission mode of the packet;
- b) update the parameters `packet-identification-last-processed` and `production-start-time` according to the arguments passed to the method;
- c) set the value of the parameter `packet-status` to ‘production started’;
- d) update the parameter `packet-buffer-available` according to the argument passed to the method;
- e) if requested by the application, send the notification ‘packet processing started’ if the state of the service instance is ‘ready’ or ‘active’.

NOTES

1. Transmission of the notification must not be requested unless a packet processing started report has been requested for the packet by the service user. This cannot be checked by the service element.

2. Due to performance considerations, the method does not perform any checks. The application must ensure that the preconditions specified in A4.3 are fulfilled.

3.1.4.4 Packet Radiated

3.1.4.4.1 The application shall call the method `PacketRadiated()` of the interface `IFSP_SIUpdate` whenever a packet completed radiation.
3.1.4.4.2 When calling the method `PacketRadiated()` the application shall provide the following information using the method arguments:

a) the identification and transmission mode of the packet for which radiation completed;

b) the time at which radiation completed.

3.1.4.4.3 The method `PacketRadiated()` shall:

a) increment the parameter `number-of-AD-packets-radiated` or `number-of-BD-packets-radiated` depending on the transmission mode of the packet;

b) if the transmission mode of the packet is ‘expedited’ set the parameters `packet-identification-last-OK` and `production-stop-time` according to the arguments passed to the method;

c) if the identification of the radiated packet equals the parameter `packet-identification-last-processed`, set the parameter `packet-status` to ‘radiated’;

d) if requested by the application, send the notification ‘packet radiated’ if the state of the service instance is ‘ready’ or ‘active’.

NOTES

1 Transmission of the notification must not be requested unless a packet radiated report has been requested for the packet by the service user. This cannot be checked by the service element.

2 Due to performance considerations, the method shall not perform any checks. The application must ensure that the preconditions specified in A4.3 are fulfilled.

3.1.4.5 Packet Acknowledged

3.1.4.5.1 The application shall call the method `PacketAcknowledged()` whenever all components of a packet have been acknowledged by the space element via the associated stream of CLCW.

3.1.4.5.2 When calling the method `PacketAcknowledged()` the application shall provide the following information using the method arguments:

a) the identification of the packet that was acknowledged;

b) the time at which the packet was acknowledged.

3.1.4.5.3 The method `PacketAcknowledged()` shall:

a) increment the parameter `number-of-packets-acknowledged`;
b) set the parameters `packet-identification-last-OK` and `production-stop-time` according to the arguments passed to the method;

c) if the identification of the acknowledged packet equals the parameter `packet-identification-last-processed`, set the parameter `packet-status` to ‘acknowledged’;

d) if requested by the application, send the notification ‘packet acknowledged’ if the state of the service instance is ‘ready’ or ‘active’.

NOTES

1 Transmission of the notification must not be requested unless a packet acknowledged report has been requested for the packet by the service user. This cannot be checked by the service element.

2 Due to performance considerations, the method shall not perform any checks. The application must ensure that the preconditions specified in A4.3 are fulfilled.

3.1.4.6 Packet Buffer Empty

3.1.4.6.1 The application shall call the method `BufferEmpty()` whenever the packet buffer becomes empty because all packets were processed.

3.1.4.6.2 The method `BufferEmpty()` shall:

   a) set the parameter `packet-buffer-available` to the value of the parameter `maximum-packet-buffer`, defined in 3.1.2.4;

   b) if requested by the application, send the notification ‘buffer empty’ if the state of the service instance is ‘ready’ or ‘active’.

NOTE – The method must not be called when the packet buffer is cleared due to one of the events for which reference [5] requires discarding of buffered packets.

3.1.4.7 Failure to Start Packet Processing

3.1.4.7.1 The application shall call the method `PacketNotStarted()` whenever processing of a packet could not be started, because:

   a) the latest production start time was expired;

   b) the production status was ‘interrupted’; or

   c) the required transition mode capability was not available.

3.1.4.7.2 When calling the method `PacketNotStarted()` the application shall provide the following information using the method arguments:
a) the identification and transmission mode of the packet which could not be started;

b) the time at which processing was attempted;

c) the reason why processing could not be started;

d) a list of identifiers of all packets that were or will be discarded because of the problem identified, excluding the packet for which the failure is reported;

NOTE – The service element shall always insert the packet that could not be started into the FSP-ASYNC-NOTIFY parameter packet-identification-list. Therefore, this packet must not be included into the list provided by the caller. If the packet for which failure is reported is the only packet that is discarded the list shall not be supplied.

e) the available buffer size.

3.1.4.7.3 The method PacketNotStarted() shall:

a) increment the parameter number-of-AD-packets-processed or number-of-BD-packets-processed depending on the transmission mode of the packet;

b) set the parameters packet-identification-last-processed and production-start-time according to the arguments passed to the method;

c) set the parameter packet-status according to reason supplied by the application:

1) if the packet could not be started because the latest production start time expired, the packet-status shall be set to 'expired';

2) if the packet could not be started because the production status was 'interrupted', the packet-status shall be set to 'production not started';

3) if the packet could not be started because the required transmission mode capability was not available, the packet-status shall be set to 'unsupported transmission mode'.

d) update the parameter packet-buffer-available according to the argument passed to the method;

e) if requested by the application, and if the state of the service instance is 'ready' or 'active':

1) if the packet could not be started because the latest production start time expired, the notification 'sldu expired' shall be sent;

2) if the packet could not be started because the production status was 'interrupted', the notification 'production interrupted' shall be sent;
3) if the packet could not be started because the required transmission mode capability was not available, the notification 'transmission mode mismatch' shall be sent.

3.1.4.8 Production Status Change

3.1.4.8.1 The application shall call the method ProductionStatusChange() whenever the production status changes, including changes of the operational sub-states.

3.1.4.8.2 If the change of the production status was caused by execution of the directive ‘abort VC’, the method VCAborted() shall be called instead of the method ProductionStatusChange().

3.1.4.8.3 When calling the method ProductionStatusChange() the application shall provide the following information using the method arguments:

a) the new value of the production status;

b) the FOP alert if the sequence-controlled service is terminated;

c) a list of identifiers of all packets that were or will be discarded because of the production status change;

NOTE – If no packets need to be discarded due to production status change, the list shall not be supplied.

d) the available buffer size.

3.1.4.8.4 The method ProductionStatusChange() shall:

a) set the parameter production-status to the value supplied by the argument;

b) if the value of the parameter packet-identification-last-processed is contained in the list of discarded packets supplied by the application:

1) if the new production status is ‘interrupted’ or ‘halted’, set the parameter packet-status to ‘interrupted’;

2) if the new production status is ‘operational BD’ or ‘operational AD suspended’, set the parameter packet-status to ‘unsupported transmission mode’.

NOTE – In all other cases, no packets shall be affected and the list of discarded packets shall not be present.

c) update the parameter packet-buffer-available according to the argument passed to the method;

d) if requested by the application, and if the state of the service instance is ‘ready’ or ‘active’:
1) if the production status changed to ‘halted’, send the notification ‘production halted’;

2) if the production status changed from ‘configured’ or ‘operational’ to 'interrupted' and the list of discarded packets is present and not empty, send the notification 'production interrupted';

3) if the production status changed from 'operational AD and BD' to 'interrupted' and the list of discarded packets is not present or empty, send the notification 'transmission mode capability change';

4) if the production status changed from ‘configured’ or ‘interrupted’ to ‘operational’, and the production status last reported to the user is not 'operational', send the notification ‘production operational’;

5) if the production status changed from 'operational AD and BD' to 'operational BD' or 'operational AD suspended' or if the production status changed from 'operational BD' or 'operational AD suspended' to 'operational AD and BD', send the notification 'transmission mode capability change';

6) if the production status changed from 'operational AD and BD' to 'operational BD' or 'operational AD suspended' and the list of discarded packets is present and not empty, send the notification 'packet transmission mode mismatch'.

NOTE – If this condition is true, the notification ‘packet transmission mode mismatch’ shall be sent in addition to and after the notification 'transmission mode capability change'.

3.1.4.8.5 The method ProductionStatusChange() shall perform the following consistency checks. If any of the checks fail, the method shall return an error code and perform no actions.

a) When the production status changes from 'configured' or 'interrupted' to 'operational', the sub-state must be 'BD'.

b) When the production status changes from operational to 'interrupted' or 'halted' and the status of the packet last processed is 'processing started', the list of affected packets must be supplied and the packet last processed must be a member of this list.

c) When the list of affected packets is supplied and is not empty, the following conditions must hold:

1) the production status must have changed;

2) the new production status must not be 'operational AD and BD' or 'configured';

3) the old production status must have been 'operational';

4) the production status must not have changed from 'operational AD suspended' to 'operational BD'.
3.1.4.8.6 If the checks identified in 3.1.4.8.5 succeed but the production status has not changed, the method shall perform no actions and shall inform the caller accordingly.

3.1.4.9 Reported Production Status

3.1.4.9.1 Whenever the service element sends one of the notifications 'production operational', 'production interrupted', or 'production halted', it shall memorize the reported status.

NOTE – This 'reported production status' shall be used to prevent that the notification 'production operational' is sent to a user that was not informed of a change to a non operational status either because the service instance was not bound when the change occurred or because no packets were affected by the production status 'interrupted'.

3.1.4.10 Execution of the Directive ‘Abort VC’

3.1.4.10.1 The application shall call the method VCAborted() whenever the directive ‘abort VC’ was executed on the virtual channel passing a list of identifiers of all packets that were discarded.

3.1.4.10.2 When calling the method VCAborted() the application shall provide the following information using the method arguments:

   a) a list of identifiers of all packets that were or will be discarded due to processing of the directive;

   NOTE – If no packets need to be discarded due to production status change, the list shall not be supplied.

   b) the available buffer size.

3.1.4.10.3 The method VCAborted() shall:

   a) set the parameter production-status to 'operational BD';

   b) if the value of the parameter packet-identification-last-processed is contained in the list of discarded packets supplied by the application and the transmission mode of that packet is 'sequence controlled', set the parameter packet status to 'interrupted';

   c) update the parameter packet-buffer-available according to the argument passed to the method;

   d) if requested by the application, send the notification ‘VC aborted’ if the state of the service instance is ‘ready’ or ‘active’.

   NOTE – If no packets were buffered or were being processed when the directive was executed, the list of discarded packets shall not be supplied.
3.1.4.11 No Invoke Directive Capability

3.1.4.11.1 The application shall call the method NoDirectiveCapability() when the service instance for which directive invocation is enabled is no longer bound due to an UNBIND operation, a PEER-ABORT operation or a protocol abort event.

3.1.4.11.2 If directive invocation is not enabled for the service instance the method NoDirectiveCapability() shall:
   a) set the parameter directive-invocation-online to 'no';
   b) if requested by the application and if the state of the service instance is ‘ready’ or ‘active’ transmit the notification ‘no invoke directive capability on this VC’.

3.1.4.11.3 If directive invocation is enabled for the service instance, the method shall perform no actions and shall inform the caller accordingly.

3.1.4.12 Invoke Directive Capability Established

3.1.4.12.1 The application shall call the method DirectiveCapabilityOnline() when a service instance for which directive invocation is enabled has bound to the provider.

3.1.4.12.2 If directive invocation is not enabled for the service instance, the method DirectiveCapabilityOnline() shall:
   a) set the parameter directive-invocation-online to 'yes';
   b) if requested by the application and if the state of the service instance is ‘ready’ or ‘active’ transmit the notification ‘invoke directive capability on this VC established’.

3.1.4.12.3 If directive invocation is enabled for the service instance, the method shall perform no actions and shall inform the caller accordingly.

3.1.4.13 Directive Execution Completed

3.1.4.13.1 The application should call the method DirectiveCompleted() when execution of a directive invoked by the operation FSP-INVOKE-DIRECTIVE completes.

3.1.4.13.2 When calling the method DirectiveCompleted() the application shall provide the following information using the method arguments:
   a) the directive identification copied from the FSP-INVOKE-DIRECTIVE invocation;
   b) the result of execution, indicating whether execution succeeded (‘positive result’) or failed (‘negative result’);
   c) in case of a negative result, the FOP alert providing the reason for the failure.

3.1.4.13.3 If requested by the caller, the method DirectiveCompleted() shall:
a) send the notification ‘positive confirm result to directive’ if the result is positive;

b) send the notification ‘negative confirm result to directive’ if the result is negative.

3.1.4.14 Event Processing Completed

3.1.4.14.1 The application should call the method EventProcCompleted() when processing of an event requested by an accepted FSP-THROW-EVENT operation completes.

3.1.4.14.2 When calling the method EventProcCompleted() the application shall provide the following information using the method arguments:

a) the event invocation identification as copied from the FSP-THROW-EVENT invocation;

b) the result of execution, indicating whether:

   1) the action list associated with the event was completely executed;
   2) at least one of the actions in the associated action list failed; or
   3) the condition associated with the event evaluated to false.

3.1.4.14.3 If requested by the caller, the method EventProcCompleted() shall:

a) send the notification ‘action list completed’ if the action list associated with the event was completely executed;

b) send the notification ‘action list not completed’ if at least one of the actions in the associated action list failed;

c) send the notification ‘event action evaluated to false’ if the condition associated with the event evaluated to false.

3.1.4.15 Consistency Checks

3.1.4.15.1 The service element shall apply the following rules for checking of consistency:

a) The methods PacketStarted(), PacketRadiated(), PacketAcknowledged(), and BufferEmpty() shall perform no checks.

   NOTE – These methods must be called frequently during nominal operation. Due to performance considerations, the service element shall fully rely on the application to ensure that the methods are used correctly. Detailed preconditions are defined in A4.3.

b) The methods DirectiveCompleted() and EventProcCompleted() shall perform no checks.
NOTE – Checking of correctness of these method invocations requires information not available to the service element. Therefore, the service element must fully rely on the application to ensure that the methods are used correctly.

c) For other methods, the service element shall verify that the arguments are consistent and that the method call is consistent with the values of the status parameters before the method was invoked. If the check fails, the service element shall proceed as follows:

1) if applying the update results in a consistent set of status parameters, the service element shall perform the update and shall send the notification (if requested) but shall return an error code to the application as a warning;

2) if an update would result in inconsistent status parameters, the service element shall not perform the update, shall not send any notifications, but shall return an appropriate error code.

NOTE – Further details concerning the checks performed and return codes passed to the caller are defined in A4.3.

3.1.5 PROCESSING OF FSP PROTOCOL DATA UNITS

NOTES

1 The service element processes FSP PDUs according to the general specifications in reference [7]. This section only addresses additional checks and processing steps defined for the FSP service. FSP specific checks defined in reference [5] but not listed in this section must be performed by the application. Section 2.2.9 provides a discussion of the borderline between the application and the service element.

2 3.1.4 defines processing requirements for update of status information and generation of notifications. Section A3 defines the checks that operation objects perform when the methods VerifyInvocationArguments() and VerifyReturnArguments() are called. Reference [7] contains specifications defining how the service element handles error codes returned by these methods.

3.1.5.1 FSP TRANSFER DATA

3.1.5.1.1 When receiving an FSP–TRANSFER–DATA invocation, the service element shall perform the following checks in addition to the checks defined in reference [7] for all PDUs. These checks shall be performed in the specified sequence:

a) if the ‘earliest production time’ and the ‘latest production time’ are both specified, the ‘earliest production time’ must not be later than the ‘latest production time’;

b) the time window defined by the ‘earliest production time’ and the ‘latest production time’ must overlap with the provision period of the service instance;
c) if the configuration parameter `segment-header` defines that segment headers are used, the value of the parameter 'MAP identifier' must be contained in the configured 'map list'. If segment headers are not used, the value of the 'MAP identifier' must be 'none';

d) the value of the parameter `transmission-mode` must match the configured permitted transmission mode;

e) if the `transmission-mode` is 'expedited', the 'acknowledged notification' must not be requested;

f) the size of the packet contained in the PDU must not be larger than the value of the configuration parameter `maximum-packet-length` allows.

3.1.5.1.2 If any of the checks defined in 3.1.5.1.1 fail, or a return PDU with a negative result must be generated because a check defined in reference [7] failed, the service element shall proceed as follows:

a) if the service element can guarantee that all preceding FSP–TRANSFER–DATA invocations have already been processed by the application, or that the PDU processed by the service element is the first FSP–TRANSFER–DATA invocation following START, the service element may generate a FSP–TRANSFER–DATA return with a negative result and transmit that to the service user;

NOTE – In that case, the service element shall use the status parameters 'expected packet identification' and `packet-buffer-available` to set the parameters of the FSP–TRANSFER–DATA return.

b) if the conditions defined in 3.1.5.1.2 item a) are not met or cannot be verified, the service element shall set the result parameter to 'negative', set the appropriate diagnostic in the operation object, and pass the operation object to the application;

c) in order to ensure that the result parameter of the operation object always has a valid reading, the service element shall set the result parameter to 'positive' if all checks performed by the service element succeeded.

NOTES

1 It is noted that this processing deviates from the standard way in which confirmed PDUs are handled by the service element. The reasons for this specification are explained in 2.2.9.3.

2 An implementation is not required to generate and transmit a FSP–TRANSFER–DATA return also when it could verify that the conditions defined in 3.1.5.1.2 item a) are met. A service element can use one of the following approaches:
– ensure that no FSP–TRANSFER–DATA invocations are queued between the service element and the application, and never pass an invocation for which a check has failed to the application;
– always pass FSP–TRANSFER–DATA invocations to the application; or
– decide on a case-by-case basis.

3 Implementations should document the approach used. Applications should always expect the service element to pass FSP–TRANSFER–DATA invocations with a negative result if substitutability of SLE API components shall be maintained.

4 Processing expected from the application is defined in 3.3.

3.1.5.2 FSP THROW EVENT

3.1.5.2.1 If an FSP–THROW–EVENT return PDU with a negative result must be generated because a check defined in reference [7] failed, the service element shall proceed as defined by the following specifications.

3.1.5.2.2 If the service element can guarantee that all preceding FSP–THROW–EVENT invocations have already been processed by the application or that the PDU processed by the service element is the first FSP–THROW–EVENT invocation following BIND, the service element may generate a FSP–THROW–EVENT return with a negative result and transmit that to the service user.

NOTE – In that case, the service element shall use the status ‘expected event invocation identifier’ to set the parameter of the FSP–THROW–EVENT return.

3.1.5.2.3 If the conditions defined in 3.1.5.2.2 are not met or cannot be verified the service element shall set the result parameter to ‘negative’, set the appropriate diagnostic in the operation object, and pass the operation object to the application.

3.1.5.2.4 In order to ensure that the result parameter of the operation object always has a valid reading, the service element shall set the result parameter to ‘positive’ if all checks performed by the service element succeeded.

NOTES

1 It is noted that this processing deviates from the standard way in which confirmed PDUs are handled by the service element. The reasons for this specification are explained in 2.2.9.3.

2 A service element shall not be required to generate and transmit a FSP–THROW–EVENT return also when it could verify that the conditions defined in 3.1.5.2.2 are met. A service element can use one of the following approaches:
– ensure that no FSP–THROW–EVENT invocations are queued between the service element and the application, and never pass an invocation for which a check has failed to the application;

– always pass FSP–THROW–EVENT invocations to the application; or

– decide on a case-by-case basis.

3 Implementations should document the approach used. Applications should always expect that the service element pass FSP–THROW–EVENT invocations with a negative result if substitutability of SLE API components shall be maintained.

4 Processing expected from the application is defined in 3.3.

### 3.1.5.3 FSP INVOKE DIRECTIVE

3.1.5.3.1 When receiving an FSP–INVOKE-DIRECTIVE invocation, the service element shall verify that invocation of directives is enabled for the service instance.

3.1.5.3.2 If invocation of directives is not enabled for the service instance, the service element shall not pass the invocation to the application but shall send a return with a negative result and the appropriate diagnostic.

3.1.5.3.3 If the invocation of directives is enabled for the service instance, but a FSP–INVOKE-DIRECTIVE return PDU with a negative result must be generated because a check defined in reference [7] failed, the service element shall proceed as follows:

a) If the service element can guarantee that all preceding FSP–INVOKE-DIRECTIVE invocations have already been processed by the application, or that the PDU processed by the service element is the first FSP–INVOKE-DIRECTIVE invocation following BIND, the service element may generate a FSP–INVOKE-DIRECTIVE return with a negative result and transmit that to the service user.

b) In that case, the service element uses the status parameter expected directive invocation identifier to set the parameter of the FSP–INVOKE-DIRECTIVE return.

c) If the conditions defined in 3.1.5.3.3 a) are not met or cannot be verified, the service element shall set the result parameter to ‘negative’, set the appropriate diagnostic in the operation object, and pass the operation object to the application.

d) In order to ensure that the result parameter of the operation object always has a valid reading, the service element shall set the result parameter to ‘positive’ if all checks performed by the service element succeeded.

NOTES

1 It is noted that this processing deviates from the standard way in which confirmed PDUs are handled by the service element. The reasons for this specification are explained in 2.2.9.3.
2 An implementation is not required to generate and transmit a FSP–INVOKE-DIRECTIVE return also when it could verify that the conditions defined in 3.1.5.3.3 item a) are met. A service element can use one of the following approaches:

– ensure that no FSP–INVOKE-DIRECTIVE invocations are queued between the service element and the application, and never pass an invocation for which a check has failed to the application;

– always pass FSP–INVOKE-DIRECTIVE invocations to the application; or

– decide on a case-by-case basis.

3 Implementations should document the approach used. Applications should always expect the service element to pass FSP–INVOKE-DIRECTIVE invocations with a negative result if substitutability of SLE API components shall be maintained.

4 Processing expected from the application is defined in 3.3.

3.1.6 SERVICE INSTANCE SPECIFIC OPERATION FACTORY

3.1.6.1.1 For FSP service instances, the interface ISLE_SIOpFactory specified in reference [7] shall support creation and configuration of operation objects for all operations specified in 3.2 with exception of the object for the operation IFSP–STATUS–REPORT.

NOTE – The initial values of parameters that shall be set for FSP specific operation objects are defined in annex A. The operation IFSP–STATUS–REPORT shall be handled autonomously by the provider-side service element. There is no need for the application to create this object.

3.2 SLE OPERATIONS

3.2.1.1.1 The component ‘SLE Operations’ shall provide operation objects for the following FSP operations in addition to those specified in reference [7]:

a) FSP–START;

b) FSP–TRANSFER–DATA;

c) FSP–ASYNC–NOTIFY;

d) FSP–STATUS–REPORT;

e) FSP–GET–PARAMETER;

f) FSP–THROW–EVENT;

g) FSP–INVOKE–DIRECTIVE.
3.2.1.1.2 The operation factory shall create the operation objects specified in 3.2.1.1.1 when the requested service type is FSP.

3.2.1.1.3 The operation factory shall additionally create the following operation objects specified in reference [7] when the requested service type is FSP:

a) SLE–BIND;
b) SLE–UNBIND;
c) SLE–PEER–ABORT;
d) SLE–STOP;
e) SLE–SCHEDULE–STATUS–REPORT.

3.3 SLE APPLICATION

NOTE – This section summarizes specific obligations of a FSP provider application using the SLE API.

3.3.1 CONFIGURATION AND UPDATE OF STATUS INFORMATION

3.3.1.1.1 Following creation of a service instance, and setting of the configuration parameters defined in reference [7], the application shall set the configuration parameters defined in 3.1.2 via the interface IFSP_SIAdmin.

3.3.1.1.2 Following creation of a service instance, the application shall initialize the FOP parameters defined in 3.1.3 via the interface IFSP_FOPMonitor and subsequently update these parameters whenever a change occurs.

3.3.1.1.3 The application shall inform the service element of all events defined in 3.1.4.2 by invocation of the appropriate methods of the interface IFSP_SIUpdate.

3.3.2 PROCESSING OF FSP TRANSFER DATA

3.3.2.1.1 When receiving a FSP–TRANSFER–DATA invocation via the interface ISLE_ServiceInform, the application shall check the result parameter of the operation object and shall perform the following steps:

a) if the result is negative, the application shall set the expected packet identification and the available buffer size and then passes the operation back to the service element using the method InitiateOpReturn() of the interface ISLE_ServiceInitiate;

b) if the result is positive, the application shall perform the checks not specified in 3.1.5 and reference [7].
1) If any of these checks fail, the application shall set the appropriate diagnostic, the expected packet identification, and the available buffer size and then pass the operation object to the service element using the method InitiateOpReturn() in the interface ISLE_ServiceInitiate.

2) If all checks succeed, the application stores the packet to the packet buffer, the application shall set a positive result, the expected packet identification, and the available buffer size and then pass the operation object back to the service element using the method InitiateOpReturn() in the interface ISLE_ServiceInitiate.

3.3.3 PROCESSING OF FSP THROW EVENT

3.3.3.1.1 When receiving a FSP–THROW–EVENT invocation via the interface ISLE_ServiceInform, the application shall check the result parameter of the operation object and perform the following steps:

a) if the result is negative, the application shall set the expected event invocation and pass the operation back to the service element using the method InitiateOpReturn() in the interface ISLE_ServiceInitiate;

b) if the result is positive, the application performs the checks not specified in 3.1.5 and reference [7].

1) If any of these checks fail, the application shall set the appropriate diagnostic and the expected event invocation identifier and then pass the operation object to the service element using the method InitiateOpReturn() in the interface ISLE_ServiceInitiate.

2) If all checks succeed, the application shall perform the required operation, set a positive result, and the expected event invocation identifier and then pass the operation object back to the service element using the method InitiateOpReturn() in the interface ISLE_ServiceInitiate.

3.3.4 PROCESSING OF FSP INVOKE DIRECTIVE

3.3.4.1.1 When receiving a FSP–INVOKE-DIRECTIVE invocation via the interface ISLE_ServiceInform, the application shall check the result parameter of the operation object and perform the following steps:

a) if the result is negative, the application shall set the expected directive invocation identifier and pass the operation back to the service element using the method InitiateOpReturn() in the interface ISLE_ServiceInitiate;

b) if the result is positive, the application shall perform the checks required.

1) If any of these checks fail, the application shall set the appropriate diagnostic and the expected directive invocation identifier and then pass the operation object to
the service element using the method `InitiateOpReturn()` in the interface `ISLE_ServiceInitiate`.

2) If all checks succeed, the application shall perform the required operation, set a positive result, and the expected directive invocation identifier, and then pass the operation object back to the service element using the method `InitiateOpReturn()` in the interface `ISLE_ServiceInitiate`.

### 3.4 SEQUENCE OF DIAGNOSTIC CODES

Reference [5] requires provider applications that do not perform checks in the sequence of the diagnostic codes defined in the specification to document the sequence in which checks are actually performed.

The specification in 3.1.5 does not preserve the sequence of the diagnostic codes defined in reference [5] for the operation FSP–TRANSFER–DATA. This section defines the actual sequence of checks performed by the API Service Element. For the checks that remain to be performed by the provider application, the sequence defined in reference [5] is maintained. Applications applying a different sequence must provide a modified documentation.

#### 3.4.1 SEQUENCE OF FSP-TRANSFER-DATA DIAGNOSTIC CODES

##### 3.4.1.1 Codes set by the API Service Element

- a) ‘duplicate invoke id’;
- b) ‘inconsistent time range’;
- c) 'invalid time';
- d) 'invalid MAP';
- e) 'invalid notification request'; and
- f) ‘packet too long’.

##### 3.4.1.2 Codes set by the Application

- a) ‘unable to process';
- b) ‘unable to store’;
- c) ‘out of sequence’;
- d) 'duplicate packet identification';
- e) ‘invalid time’;
- f) 'conflicting production time intervals';
- g) ‘late sldu’;
h) ‘invalid delay time’;
i) 'invalid transmission mode';
j) 'unsupported packet version';
k) 'incorrect packet type';
l) 'invalid packet apid'; and
m) 'other reason'.
ANNEX A

FSP SPECIFIC INTERFACES

(This annex is part of the Recommended Practice)

A1 INTRODUCTION

This annex specifies FSP specific

a) data types;

b) interfaces for operation objects; and

c) interfaces for service instances.

The specification of the interfaces follows the design patterns, conventions and the additional conventions described in reference [6].

The presentation uses the notation and syntax of the C++ programming language as specified in reference [7].
A2  FSP TYPE DEFINITIONS

File  FSP_Types.h

The following types have been derived from the ASN.1 module CCSDS-SLE-TRANSFER-FSP-STRUCTURES in reference [5]. The source ASN.1 type is indicated in brackets. For all enumeration types a special value ‘invalid’ is defined, which is returned if the associated value in the operation object has not yet been set, or is not applicable in case of a choice.

Absolute Priority [AbsolutePriority]

typedef struct FSP_AbsolutePriority
{
   unsigned int mapOrVc;        /* 0 to 63 */
   unsigned int priority;       /* 1 (highest) to 64 (lowest) */
} FSP_AbsolutePriority;

An entry in the priority list used for multiplexing of MAPs and VCs.

Blocking Usage [BlockingUsage]

typedef enum FSP_BlockingUsage
{
   fspAU_permitted        =  0,
   fspAU_notPermitted     =  1,
   fspAU_invalid          = -1
} FSP_BlockingUsage;

Application Identifier (APID)

typedef unsigned long FSP_ApId;       /* 0 to 2047 */

Packet Buffer Size [BufferSize]

typedef unsigned long FSP_BufferSize;

Size of the packet buffer or the remaining free space in the buffer measured in octets.

Packet Identification [PacketIdentification]

typedef unsigned long FSP_PacketId;

Directive Identification

typedef unsigned long FSP_DirectiveId;

Identifier of a Thrown Event [EventInvocationId]

typedef unsigned long FSP_EventInvocationId;
Directive [FspInvokeDirectiveInvocation]

typedef enum FSP_Directive
{
    fspDV_initiateADwithoutCLCW = 0,
    fspDV_initiateADwithCLCW = 1,
    fspDV_initiateADwithUnlock = 2,
    fspDV_initiateADwithSetVR = 3,
    fspDV_terminateAD = 4,
    fspDV_resumeAD = 5,
    fspDV_setVS = 6,
    fspDV_setPopSlidingWindow = 7,
    fspDV_setT1Initial = 8,
    fspDV_setTransmissionLimit = 9,
    fspDV_setTimeoutType = 10,
    fspDV_abortVC = 11,
    fspDV_modifyMapMuxControl = 12,
    fspDV_invalid = -1
} FSP_Directive;

MAP or VC Identification [MapOrVcId]

typedef unsigned int FSP_MapOrVcId;    /* 0 to 63 */

MAP Identification [MapId]

typedef FSP_MapOrVcId FSP_MapId;

VC Identification

typedef FSP_MapOrVcId FSP_VcId;

Multiplexing Scheme [MuxScheme]

typedef enum FSP_MuxScheme
{
    fspMS_fifo = 0,
    fspMS_absolutePriority = 1,
    fspMS_pollingVector = 2,
    fspMS_invalid = -1
} FSP_MuxScheme;

Timeout Type [FspGetParameter]

typedef enum FSP_TimeoutType
{
    fspTT_generateAlert = 0,
    fspTT_suspendAD = 1,
    fspTT_invalid = -1
} FSP_TimeoutType;

Timeout Type [FspInvokeDirectiveParameter]

typedef enum FSP_DirectiveTimeoutType
{
    fspDTT_terminateAD = 0,
    fspDTT_suspendAD = 1,
    fspDTT_invalid = -1
} FSP_DirectiveTimeoutType;
The Timeout Type used in the Invoke Directive invocation.

**Transmission Mode [TransmissionMode]**

typedef enum FSP_TransmissionMode
{
    fspTM_sequenceControlled   =  0, /* AD mode */
    fspTM_expedited            =  1, /* BD mode */
    fspTM_sequenceControlledUnblock =  2, /* unblock AD */
    fspTM_invalid              = -1
} FSP_TransmissionMode;

**Transmission Mode [PermittedTransmissionMode]**

typedef enum FSP_PermittedTransmissionMode
{
    fspPTM_sequenceControlled   =  0,
    fspPTM_expedited            =  1,
    fspPTM_any                  =  2,
    fspPTM_invalid              = -1
} FSP_PermittedTransmissionMode;

**FSP Start Diagnostic [DiagnosticFspStart]**

typedef enum FSP_StartDiagnostic
{
    fspSTD_outOfService          =  0,
    fspSTD_unableToComply        =  1,
    fspSTD_productionTimeExpired =  2,
    fspSTD_invalid               = -1
} FSP_StartDiagnostic;

**FSP Transfer Data Diagnostic [DiagnosticFspTransferData]**

typedef enum FSP_TransferDataDiagnostic
{
    fspXFD_unableToProcess       =  0,
    fspXFD_unableToStore         =  1,
    fspXFD_packetIdOutOfSequence =  2,
    fspXFD_dupeicateIdentification =  3,
    fspXFD_inconsistentTimeRange =  4,
    fspXFD_invalidTime           =  5,
    fspXFD_conflictingProductionTimeIntervals =  6,
    fspXFD_lateSldu              =  7,
    fspXFD_invalidDelayTime      =  8,
    fspXFD_invalidTransmissionMode =  9,
    fspXFD_invalidMap            = 10,
    fspXFD_invalidNotificationRequest = 11,
    fspXFD_packetTooLong         = 12,
    fspXFD_unsupportedPacketVersion = 13,
    fspXFD_incorrectPacketType   = 14,
    fspXFD_invalidPacketApid     = 15,
    fspXFD_invalid               = -1
} FSP_TransferDataDiagnostic;

**FSP Get Parameter Diagnostic [DiagnosticFspGetParameter]**

typedef enum FSP_GetParameterDiagnostic
{
    fspGP_unknownParameter       =  0,

fspGP_invalid         =   -1
} FSP_GetParameterDiagnostic;

---

**FSP Invoke Directive Diagnostic [DiagnosticFspInvokeDirective]**

typedef enum FSP_InvokeDirectiveDiagnostic
{
    fspID_directiveInvocationNotAllowed        =   0,
    fspID_directiveIdentificationOutOfSequence =   1,
    fspID_directiveError                       =   2,
    fspID_invalid                              =  -1
} FSP_InvokeDirectiveDiagnostic;

---

**FSP Throw Event Diagnostic [DiagnosticFspThrowEvent]**

typedef enum FSP_ThrowEventDiagnostic
{
    fspTED_operationNotSupported      =   0,
    fspTED_outOfSequence              =   1,
    fspTED_noSuchEvent                =   2,
    fspTED_invalid                    =  -1
} FSP_ThrowEventDiagnostic;

---

**FSP Service Parameters [FspParameterName]**

typedef enum FSP_ParameterName
{
    fspPN_blockingTimeoutPeriod          =   0,
    fspPN_blockingUsage                  =   1,
    fspPN_apidList                       =   2,
    fspPN_deliveryMode                   =   6,
    fspPN_directiveInvocationEnabled     =   7,
    fspPN_expectedDirectiveId            =   8,
    fspPN_expectedEventInvocationId      =   9,
    fspPN_expectedSlduIdentification     =  10,
    fspPN_fopSlidingWindow               =  11,
    fspPN_fopState                       =  12,
    fspPN_mapList                        =  16,
    fspPN_mapMuxControl                  =  17,
    fspPN_mapMuxScheme                   =  18,
    fspPN_maximumFrameLength             =  19,
    fspPN_maximumPacketLength            =  20,
    fspPN_reportingCycle                 =  26,
    fspPN_returnTimeoutPeriod            =  29,
    fspPN_segmentHeader                  =  32,
    fspPN_timeoutType                    =  35,
    fspPN_timerInitial                   =  36,
    fspPN_transmissionLimit              =  37,
    fspPN_transmitterFrameSequenceNumber =  38,
    fspPN_vcMuxControl                   =  39,
    fspPN_vcMuxScheme                    =  40,
    fspPN_virtualChannel                 =  41,
    fspPN_permittedTransmissionMode      =  107,
    fspPN_directiveInvocationOnline      =  108,
    fspPN_invalid                        =  -1
} FSP_ParameterName;

The parameter name values are taken from the type ParameterName in CCSDS-SLE-TRANSFER-SERVICE-COMMON-TYPES
FOP Alert [FopAlert]

typedef enum FSP_FopAlert
{
    fspFA_noAlert = 0,
    fspFA_limit = 1,
    fspFA_lockOutDetected = 2,
    fspFA_synch = 3,
    fspFA_invalidNR = 4,
    fspFA_Clcw = 5,
    fspFA_lowerLayerOutOfSync = 6,
    fspFA_terminateAD = 7,
    fspFA_invalid = -1
} FSP_FopAlert;

Packet Status [PacketStatus]

typedef enum FSP_PacketStatus
{
    fspST_acknowledged = sleFDS_acknowledged,
    fspST_radiated = sleFDS_radiated,
    fspST_productionStarted = sleFDS_productionStarted,
    fspST_productionNotStarted = sleFDS_productionNotStarted,
    fspST_expired = sleFDS_expired,
    fspST_unsupportedTransmissionMode = sleFDS_unsupportedTransmissionMode,
    fspST_interrupted = sleFDS_interrupted,
    fspST_invalid = -1
} FSP_PacketStatus;

Describes the state of the last processed packet. It is defined as a subset of the type
SLE_ForwardDuStatus specified in reference [5].

Production Status [ProductionStatus]

typedef enum FSP_ProductionStatus
{
    fspPS_configured = 0,
    fspPS_operationalBd = 1,
    fspPS_operationalAdAndBd = 2,
    fspPS_operationalAdSuspended = 3,
    fspPS_interrupted = 4,
    fspPS_halted = 5,
    fspPS_invalid = -1
} FSP_ProductionStatus;

The status of the FSP production engine

FOP State [FspGetParameter]

typedef enum FSP_FopState
{
    fspFS_active = 0,
    fspFS_retransmitWithoutWait = 1,
    fspFS_retransmitWithWait = 2,
    fspFS_initialisingWithoutBCFrame = 3,
    fspFS_initialisingWithBCFrame = 4,
    fspFS_initial = 5,
    fspFS_invalid = -1
} FSP_FopState;
The result of processing a thrown event

Notification Type [FspNotification]

typedef enum FSP_NotificationType
{
    fspNT_packetProcessingStarted = 0,
    fspNT_packetRadiated = 1,
    fspNT_packetAcknowledged = 2,
    fspNT_slduExpired = 3,
    fspNT_packetTransmissionModeMismatch = 4,
    fspNT_transmissionModeCapabilityChange = 5,
    fspNT_bufferEmpty = 6,
    fspNT_noInvokeDirectiveCapabilityOnThisVc = 7,
    fspNT_positiveConfirmResponseToDirective = 8,
    fspNT_negativeConfirmResponseToDirective = 9,
    fspNT_vcAborted = 10,
    fspNT_productionInterrupted = 11,
    fspNT_productionHalted = 12,
    fspNT_productionOperational = 13,
    fspNT_actionListCompleted = 14,
    fspNT_actionListNotCompleted = 15,
    fspNT_eventConditionEvFalse = 16,
    fspNT_invokeDirectiveCapabilityOnThisVC = 17,
    fspNT_invalid = -1
} FSP_NotificationType;

FSP Failure

typedef enum FSP_Failure
{
    fspF_expired = 0,
    fspF_interrupted = 1,  /* production interrupted */
    fspF_modeMismatch = 2  /* transmission mode mismatch */
} FSP_Failure;
A3  FSP OPERATION OBJECTS

A3.1  FSP START OPERATION

Name   IFSP_Start
GUID   {1D0CBEE0-E896-11d4-9F17-00104B4F22C0}
Inheritance:  IUnknown  –  ISLE_Operation  –  ISLE_ConfirmedOperation
File    IFSP_Start.H

The interface provides access to the parameters of the confirmed operation FSP START.

Synopsis

#include <FSP_Types.h>
#include <ISLE_ConfirmedOperation.H>
interface ISLE_Time;
#define IID_IFSP_Start_DEF { 0x1d0cbee0, 0xe896, 0x11d4, \
{ 0x9f, 0x17, 0x0, 0x10, 0x4b, 0x4f, 0x22, 0xc0 } }
interface IFSP_Start : ISLE_ConfirmedOperation 
{
  virtual FSP_PacketId
    Get_FirstPacketId() const = 0;
  virtual const ISLE_Time*
    Get_StartProductionTime() const = 0;
  virtual const ISLE_Time*
    Get_StopProductionTime() const = 0;
  virtual FSP_StartDiagnostic
    Get_StartDiagnostic() const = 0;
  virtual void
    Set_FirstPacketId( FSP_PacketId id ) = 0;
  virtual void
    Set_StartProductionTime( const ISLE_Time& startTime ) = 0;
  virtual void
    Put_StartProductionTime( ISLE_Time* pstartTime ) = 0;
  virtual void
    Set_StopProductionTime( const ISLE_Time& stopTime ) = 0;
  virtual void
    Put_StopProductionTime( ISLE_Time* pstopTime ) = 0;
  virtual void
    Set_StartDiagnostic( FSP_StartDiagnostic diag ) = 0;
};

Methods

FSP_PacketId Get_FirstPacketId() const;

Returns the first packet identification that the provider shall expect.

const ISLE_Time* Get_StartProductionTime() const;

Returns a pointer to the production start time if that parameter has been set. If the parameter
has not been specified returns a NULL pointer.
const ISLE_Time* Get_StopProductionTime() const;

Returns a pointer to the production stop time if that parameter has been set. If the parameter has not been specified returns a NULL pointer.

FSP_StartDiagnostic Get_StartDiagnostic() const;

Returns the diagnostic code.

Precondition: the result is negative, and the diagnostic type is set to ‘specific’.

void Set_FirstPacketId( FSP_PacketId id );

Sets the first packet identification the provider shall accept.

void Set_StartProductionTime( const ISLE_Time& startTime );

Sets the production start time to a copy of the input argument.

void Put_StartProductionTime( ISLE_Time* pstartTime );

Stores the input argument to the parameter production start time.

void Set_StopProductionTime( const ISLE_Time& stopTime );

Sets the production stop time to a copy of the input argument.

void Put_StopProductionTime( ISLE_Time* pstopTime );

Stores the input argument to the parameter production stop time.

void Set_StartDiagnostic( FSP_StartDiagnostic diag );

Sets the result to ‘negative’, the diagnostic type to ‘specific’, and stores the value of the diagnostic code passed by the argument.

Initial Values of Operation Parameters after Creation

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Created directly</th>
<th>Created by Service Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>first packet identification</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>start production time</td>
<td>NULL (not used)</td>
<td>NULL (not used)</td>
</tr>
<tr>
<td>stop production time</td>
<td>NULL (not used)</td>
<td>NULL (not used)</td>
</tr>
<tr>
<td>START diagnostic</td>
<td>‘invalid’</td>
<td>‘invalid’</td>
</tr>
</tbody>
</table>
Checking of Invocation Parameters

No checks beyond those defined by inherited interfaces are performed.

Checking of Return Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>start production time</td>
<td>must not be NULL; if the start and the stop time are used, must be earlier than stop time</td>
</tr>
<tr>
<td>stop production time</td>
<td>if the start and the stop time are used, must be later than stop time</td>
</tr>
<tr>
<td>START diagnostic</td>
<td>must not be 'invalid' if the result is 'negative' and the diagnostic type is 'specific'</td>
</tr>
</tbody>
</table>

Additional Return Codes for `VerifyReturnArguments`

- **SLE_E_MISSINGARG** specification of the start production time is missing.
A3.2 FSP TRANSFER DATA OPERATION

Name IFSP_TransferData
GUID {91DCEBA0-E896-11d4-9F17-00104B4F22C0}
Inheritance: IUnknown – ISLE_Operation – ISLE_ConfirmedOperation
File IFSP_TransferData.H

The interface provides access to the parameters of the confirmed operation FSP-TRANSFER-DATA.

Synopsis

```c
#include <FSP_Types.h>
#include <ISLE_ConfirmedOperation.H>
interface ISLE_Time;
#define IID_IFSP_TransferData_DEF { 0x91dceba0, 0xe896, 0x11d4, 
{ 0x9f, 0x17, 0x0, 0x10, 0x4b, 0x4f, 0x22, 0xc0 } }

interface IFSP_TransferData : ISLE_ConfirmedOperation

virtual void
    Set_PacketBufferAvailable( FSP_BufferSize bufAvail ) = 0;
virtual void
    Set_TransferDataDiagnostic( FSP_TransferDataDiagnostic diagnostic) = 0;
};

Methods

FSP_PacketId Get_PacketId() const;

Returns the packet identification.

FSP_PacketId Get_ExpectedPacketId() const;

Returns the next expected packet identification. If the parameter has not been set returns zero.

const ISLE_Time* Get_EarliestProdTime() const;

Returns a pointer to the earliest production time, if the parameter has been specified. If the parameter is not set, returns a NULL pointer.

const ISLE_Time* Get_LatestProdTime() const;

Returns a pointer to the latest production time, if the parameter has been specified. If the parameter is not set, returns a NULL pointer.

SLE_Duration Get_DelayTime() const;

Returns the parameter delay time.
FSP_TransmissionMode Get_TransmissionMode() const;

Returns the transmission mode parameter.

virtual bool Get_MapIdUsed()

Returns TRUE if the MAP ID parameter is used and not set to 'none'. Otherwise returns FALSE.

FSP_MapId Get_MapId() const;

Returns the MAP identifier if set in the object.

Precondition: Get_MapIdUsed() returns TRUE.

SLE_YesNo Get_Blocking() const;

Returns the specification whether packet blocking should be applied.

SLE_SlduStatusNotification Get_ProcessingStartedNotification() const;

Returns the specification whether a notification shall be sent when processing of the packet was started.

SLE_SlduStatusNotification Get_RadiatedNotification() const;

Returns the specification whether a notification shall be sent when the packet was radiated.

SLE_SlduStatusNotification Get_AcknowledgedNotification() const;

Returns the specification whether a notification shall be sent when the packet was received on board.

const SLE_Octet* Get_Data( size_t& length ) const;

Returns a pointer to the packet data in the object. The data must neither be modified nor deleted by the caller.

Arguments

length the number of bytes in the packet

SLE_Octet* Remove_Data( size_t& length );
Returns a pointer to the packet data and removes the data from the object. The client is expected to delete the data when they are no longer needed.

**Arguments**

- **length**  
  the number of bytes in the packet

```c
FSP_BufferSize Get_PacketBufferAvailable() const;
```

Returns the available packet buffer size in bytes if the argument has been set. If the parameter has not been set returns zero.

```c
FSP_TransferDataDiagnostic Get_TransferDataDiagnostic() const;
```

Returns the diagnostic code.

**Precondition:** the result is negative, and the diagnostic type is set to ‘specific’.

```c
void Set_PacketId( FSP_PacketId id );
```

Sets the packet identification for the packet transferred.

```c
void Set_ExpectedPacketId( FSP_PacketId id );
```

Sets the next expected packet identification.

```c
void Set_EarliestProdTime( const ISLE_Time& earliestTime );
```

Sets the earliest production time to a copy of the input argument.

```c
void Put_EarliestProdTime( ISLE_Time* pearliestTime );
```

Stores the input argument to the parameter earliest production time.

```c
void Set_LatestProdTime( const ISLE_Time& latestTime );
```

Sets the latest production time to a copy of the input argument.

```c
void Put_LatestProdTime( ISLE_Time* platestTime );
```

Stores the input argument to the parameter latest production time.

```c
void Set_DelayTime( SLE_Duration delay );
```

Sets the parameter delay time.
void Set_TransmisionMode( FSP_TransmissionMode mode );

Sets the parameter transmission mode to the value of the argument.

void Set_MapId( FSP_MapId id );

Sets the parameter 'MAP identifier' to the value of the argument. The argument must be in the range 0 to 63. The method must not be invoked when segment headers are not used.

void Set_Blocking( SLE_YesNo );

Sets the parameter 'blocking' to the value of the argument.

void Set_ProcessingStartedNotification( SLE_SlduStatusNotification ntf );

Sets the parameter 'processing started notification' to the value of the argument.

void Set_RadiatedNotification( SLE_SlduStatusNotification ntf );

Sets the parameter 'radiated notification' to the value of the argument.

void Set_AcknowledgedNotification( SLE_SlduStatusNotification ntf );

Sets the parameter 'acknowledged notification' to the value of the argument.

void Set_Data( size_t length, const SLE_Octet* pdata );

Copies length bytes from the address pdata to the internal packet data parameter.

Arguments

pdata     pointer to the packet data
length    the number of bytes in the packet

void Put_Data( size_t length, SLE_Octet* data );

Stores the packet data to the object. The operation object will eventually delete the data buffer.

Arguments

pdata     pointer to the packet data
length    the number of bytes in the packet
void Set_PacketBufferAvailable( FSP_BufferSize bufAvail );

Sets the available packet buffer size in byte.

void
Set_TransferDataDiagnostic( FSP_TransferDataDiagnostic diagnostic );

Sets the result to ‘negative’, the diagnostic type to ‘specific’, and stores the value of the diagnostic code passed by the argument.

virtual void
  Set_ProdustionStatus( FSP_ProdustionStatus status ) = 0;
};

Methods

FSP_NotificationType Get_NotificationType() const;

Returns the notification type.

FSP_DirectiveId Get_DirectiveExecutedId() const;

Returns the identification of the executed directive to which the notification refers.

Precondition: notification type is one of ‘positive confirm response to directive’, or ‘negative
confirm response to directive’.

FSP_EventInvocationId Get_EventThrownId() const;

Returns the identification of the thrown event to which the notification refers.

Precondition: notification type is one of ‘action list completed’, ‘action list not completed’,
‘event condition evaluate to false’.

const FSP_PacketId* Get_PacketIdentificationList( int& size ) const;

Returns the list of identifiers of affected packets. If the parameter is present but the list is
empty, or if the parameter is not present, returns a NULL pointer.

Precondition: notification type is one of ‘packet processing started’, ‘packet radiated’, ‘packet acknowledged’,

Arguments

size number of packet identifiers in the list
FSP_FopAlert Get_FopAlert() const;

Returns the FOP Alert parameter.

**Precondition:** notification type is ‘transmission mode capability change’ or ‘negative confirm response to directive’.

bool Get_PacketsProcessed() const;

Returns true if at least one packet has started processing, false otherwise.

FSP_PacketId Get_PacketLastProcessed() const;

Returns the identification of the last packet for which processing started.

**Precondition:** Get_PacketsProcessed() returns true.

const ISLE_Time* Get_ProductionStartTime() const;

Returns a pointer to the production start time of the last packet processed if the parameter has been set. Otherwise returns a NULL pointer.

**Precondition:** Get_PacketsProcessed() returns true.

FSP_Status Get_PacketStatus() const;

Returns the status of the last packet processed.

**Precondition:** Get_PacketsProcessed() returns true.

bool Get_PacketsCompleted() const;

Returns true if at least one packet has successfully completed processing (i.e. radiated for BD and acknowledged for AD), false otherwise.

FSP_PacketId Get_PacketLastOk() const;

Returns the identification of the last packet that successfully completed processing.

**Precondition:** Get_PacketsCompleted() returns true.

const ISLE_Time* Get_ProductionStopTime() const;

Returns a pointer to the production stop time of the last packet that successfully completed processing if the parameter has been set. Otherwise returns a NULL pointer.
Precondition: Get_PacketsCompleted() returns true.

**FSP_ProductionStatus** Get_ProductionStatus() const;

Returns the current value of the production status.

**void Set_NotificationType( FSP_NotificationType notifyType );**

Sets the notification type.

**void Set_DirectiveExecutedId( FSP_DirectiveId id );**

Sets the identification of the executed directive to which the notification refers.

**void Set_EventThrownId( FSP_EventInvocationId id );**

Sets the identification of the thrown event to which the notification refers.

**void Set_PacketIdentificationList( const FSP_PacketId* list, int size );**

Copies the list of packet identifiers passed as argument to the parameter 'packet identification list'. If the list must be supplied for the notification but does not contain any entries, the size argument must be set to zero. In this special case, a NULL pointer can be supplied.

**Arguments**

`size` number of packet identifiers in the list

**void Put_PacketIdentificationList( FSP_PacketId* list, int size );**

Stores the list of packet identifiers passed as argument to the parameter 'packet identification list'. If the list must be supplied for the notification but does not contain any entries, the size argument must be set to zero. In this special case, a NULL pointer can be supplied.

**Arguments**

`size` number of packet identifiers in the list

**void Set_FopAlert( FSP_FopAlert alert );**

Sets the parameter FOP alert to the value passed as argument.

**void Set_PacketLastProcessed( FSP_PacketId id ) = 0;**

Sets the identification of the last packet processed and sets ‘packets processed’ to true.
void Set_ProductionStartTime( const ISLE_Time& startTime );
Sets the production start time of the last processed packet to a copy of the input argument.

void Put_ProductionStartTime( ISLE_Time* pstartTime );
Stores the input argument to the parameter production start time of the packet last processed.

void Set_PacketStatus( FSP_Status status );
Sets the status of the last processed packet.

void Set_PacketLastOk( FSP_PacketId id );
Sets the identification of the last packet that completed processing and sets 'packets completed to true.

void Set_ProductionStopTime( const ISLE_Time& stopTime );
Sets the radiation stop time of the last packet that completed processing to a copy of the input argument.

void Put_ProductionStopTime( ISLE_Time* pstopTime );
Stores the input argument to the parameter radiation stop time of the packet last radiated.

void Set_ProductionStatus( FSP_ProductionStatus status );
Sets the value of the parameter production status.

};

Methods

bool Get_PacketsProcessed() const;

Returns true if at least one packet started processing. This condition is true if the number of AD and BD packets processed are not both zero.

FSP_PacketId Get_PacketLastProcessed() const;

Returns the identification of the packet last processed.

Precondition: Get_PacketsProcessed() returns true.

const ISLE_Time* Get_ProductionStartTime() const;

Returns a pointer to the radiation start time of the last packet processed, if the parameter has been set. Otherwise returns a NULL pointer.

FSP_Status Get_PacketStatus() const;

Returns the status of the last packet for which processing started.

Precondition: Get_PacketsProcessed() returns true.

bool Get_PacketsCompleted() const;
Returns true if at least one packet successfully completed processing. The condition is true if the number of BD packets radiated and the number of AD packets acknowledged are not both zero.

\[ \text{FSP\_PacketId Get\_PacketLastOk()} \text{ const;} \]

Returns the identification of the last packet which successfully completed processing.

**Precondition:** Get\_PacketsCompleted() returns true.

\[ \text{const ISLE\_Time* Get\_ProductionStopTime()} \text{ const;} \]

Returns a pointer to the production stop time of the last packet that successfully completed processing, if the parameter has been set. Otherwise returns a NULL pointer.

\[ \text{FSP\_ProductionStatus Get\_ProductionStatus()} \text{ const;} \]

Returns the current value of the production status.

\[ \text{unsigned long Get\_NumberOfADPacketsReceived()} \text{ const;} \]

Returns the number of AD packets that have been received and accepted by the provider.

\[ \text{unsigned long Get\_NumberOfBDPacketsReceived()} \text{ const;} \]

Returns the number of BD packets that have been received and accepted by the provider.

\[ \text{unsigned long Get\_NumberOfADPacketsProcessed()} \text{ const;} \]

Returns the number of AD packets for which processing was started.

\[ \text{unsigned long Get\_NumberOfBDPacketsProcessed()} \text{ const;} \]

Returns the number of BD packets for which processing was started.

\[ \text{unsigned long Get\_NumberOfADPacketsRadiated()} \text{ const;} \]

Returns the number of AD packets that have been successfully radiated by the provider.

\[ \text{unsigned long Get\_NumberOfBDPacketsRadiated()} \text{ const;} \]

Returns the number of BD packets that have been successfully radiated by the provider.

\[ \text{unsigned long Get\_NumberOfPacketsAcknowledged()} \text{ const;} \]
Returns the number of packets that have been acknowledged via the CLCW.

\[ \text{FSP_BufferSize Get_PacketBufferAvailable() const;} \]

Returns the size of the available packet buffer in octets.

\[ \text{void Set_ProductionStartTime( const ISLE_Time& start\_time );} \]

Sets the production start time of the packet last processed to a copy of the input argument.

\[ \text{void Put_ProductionStartTime( ISLE\_Time* pstart\_time );} \]

Stores the input argument to the parameter production start time.

\[ \text{void Set_PacketStatus( FSP\_Status status );} \]

Sets the status of the packet last processed.

\[ \text{void Set_PacketLastOk( FSP\_PacketId id );} \]

Sets the identification of the last packet, which successfully completed production.

\[ \text{void Set_ProductionStopTime( const ISLE\_Time& stop\_time );} \]

Sets the production stop time of the packet last that successfully completed production to a copy of the input argument.

\[ \text{void Put_ProductionStopTime( ISLE\_Time* pstop\_time );} \]

Stores the input argument to the parameter production stop time.

\[ \text{void Set_ProductionStatus( FSP\_ProductionStatus status );} \]

Sets the value of the production status.

\[ \text{void Set_NumberOfADPacketsReceived( unsigned long num\_recv );} \]

Sets the number of AD packets received and accepted by the provider.

\[ \text{void Set_NumberOfBDPacketsReceived( unsigned long num\_recv );} \]

Sets the number of BD packets received and accepted by the provider.

\[ \text{void Set_NumberOfADPacketsProcessed( unsigned long num\_proc );} \]
Sets the number of AD packets for which processing was started.

```c
void Set_NumberOfBDPacketsProcessed( unsigned long numProc );
```

Sets the number of BD packets for which processing was started.

```c
void Set_NumberOfADPacketsRadiated( unsigned long numRad );
```

Sets the number of AD packets successfully radiated by the provider.

```c
void Set_NumberOfBDPacketsRadiated( unsigned long numRad );
```

Sets the number of BD packets successfully radiated by the provider.

```c
void Set_NumberOfPacketsAcknowledged( unsigned long numRad );
```

Sets the number of packets acknowledged via the CLCW.

```c
void Set_PacketBufferAvailable( FSP_BufferSize size );
```

Sets the available buffer size.

### Initial Values of Operation Parameters after Creation

The interface `ISLE_SIOpFactory` does not support creation of status report operation objects, as this operation is handled by the service instance internally.

<table>
<thead>
<tr>
<th>Parameter</th>

Methods

FSP_ParameterName Get_RequestedParameter() const;

Returns the parameter for which the value shall be reported.

FSP_ParameterName Get_ReturnedParameter() const;

Returns the parameter for which the value is reported. Following the return, this must be identical to the result of Get_RequestedParameter().
const FSP_ApId* Get_ApIdList( int& size ) const;

Returns an array of Application Process Identifiers to which the service instance has access.

Precondition: the returned parameter is apid-list.

Arguments

size set to the number of identifiers in the list

unsigned long Get_BlockingTimeout() const;

Returns timeout period in milliseconds for blocking of packets. If blocking is not used, returns zero.

Precondition: the returned parameter is blocking-timeout-period.

FSP_BlockingUsage Get_BlockingUsage() const;

Returns a specification whether blocking of packets is permitted.

Precondition: the returned parameter is blocking-usage.

SLE_DeliveryMode Get_DeliveryMode() const;

Returns 'forward online'.

Precondition: the returned parameter is delivery-mode.

SLE_YesNo Get_DirectiveInvocationEnabled() const;

Returns whether this service instance is authorized to invoke the FSP-INVOKE-DIRECTIVE operation.

Precondition: the returned parameter is directive-invocation-enabled.

SLE_YesNo Get_DirectiveInvocationOnline() const;

Returns 'yes' if a service instance with directive invocation capability is currently bound to the service provider and 'no' otherwise.

Precondition: the returned parameter is directive-invocation-online.

FSP_DirectiveId Get_ExpectedDirectiveId() const;

Returns the next expected directive identification.
Precondition: the returned parameter is expected-directive-identification.

**FSP_EventInvocationId Get_ExpectedEventInvocationId() const;**

Returns the next expected event invocation identifier.

**Precondition:** the returned parameter is expected-event-invocation-identification.

**FSP_PacketId Get_ExpectedSlduId() const;**

Returns the next expected packet identification.

**Precondition:** the returned parameter is expected-sldu-identification and the value has been set via a START invocation or as result of a TRANSFER DATA operation.

**unsigned long Get_FopSlidingWindow() const;**

Returns the width of the FOP sliding window.

**Precondition:** the returned parameter is fop-sliding-window.

**FSP_FopState Get_FopState() const;**

Returns the state of the FOP.

**Precondition:** the returned parameter is fop-state.

**const FSP_MapId* Get_MapList( int& size ) const;**

Returns an array of MAP identifiers for the MAPs that can be used by the service instance. If no MAPs are used returns a NULL pointer.

**Precondition:** the returned parameter is map-list.

Arguments

*size* set to the number of identifiers in the list

**const FSP_AbsolutePriority* Get_MapPriorityList(int& size) const;**

Returns the priority specification for multiplexing on MAPs if the multiplexing scheme is 'absolute priority'. The priority specification is an array of 'map id' - 'priority' pairs. If the multiplexing scheme is FIFO or 'polling vector', or if MAPs are not used, returns NULL.

**Precondition:** the returned parameter is map-multiplexing-control.
Arguments

size  set to the number of 'map id' - 'priority' pairs in the list

\texttt{const FSP\_MapId* Get\_MapPollingVector( int& size ) const;}

Returns the polling vector for multiplexing on MAPs if the multiplexing scheme is 'polling vector'. The polling vector is an array of MAP identifiers. If the multiplexing scheme is FIFO or 'absolute priority', or if MAPs are not used, returns NULL.

\textbf{Precondition:} the returned parameter is map-multiplexing-control.

Arguments

size  set to the number of identifiers in the list

\texttt{FSP\_MuxScheme Get\_MapMuxScheme() const;}

Returns the multiplexing scheme in effect for MAPs. If MAPs are not used, the parameter is set to ‘invalid’.

\textbf{Precondition:} the returned parameter is map-multiplexing-scheme.

\texttt{unsigned long Get\_MaxFrameLength() const;}

Returns the maximum length of a TC frame in octets.

\textbf{Precondition:} the returned parameter is maximum-frame-length.

\texttt{unsigned long Get\_MaxPacketLength() const;}

Returns the maximum length of a packet in octets.

\textbf{Precondition:} the returned parameter is maximum-packet-length.

\texttt{FSP\_PermittedTransmissionMode Get\_PermittedTransmissionMode() const;}

Returns the permitted transmission mode.

\textbf{Precondition:} the returned parameter is permitted-transmission-mode.

\texttt{unsigned long GetReportingCycle() const;}

Returns the reporting cycle requested by the user if periodic reporting is active. If reporting is not active, returns zero.
Precondition: the returned parameter is `reporting-cycle`.

```cpp
unsigned long Get_ReturnTimeoutPeriod() const;
```

Returns the return timeout period used by the provider.

Precondition: the returned parameter is `return-timeout-period`.

```cpp
SLE_YesNo Get_SegmentHeaderPresent() const;
```

Returns whether segment headers are used.

Precondition: the returned parameter is `segment-header`.

```cpp
FSP_TimeoutType Get_TimeoutType() const;
```

Returns the FOP timeout type parameter, which specifies how the FOP reacts when the maximum number of retransmissions has been exceeded.

Precondition: the returned parameter is `timeout-type`.

```cpp
unsigned long Get_TimerInitial() const;
```

Returns the initial value of the countdown timer in microseconds when an AD or BC frame is transmitted.

Precondition: the returned parameter is `timer-initial`.

```cpp
unsigned long Get_TransmissionLimit() const;
```

Returns the maximum number of times the first frame on the Sent-Queue may be transmitted.

Precondition: the returned parameter is `transmission-limit`.

```cpp
unsigned long Get_TransmitterFrameSequenceNumber() const;
```

Returns the Transmitter Frame Sequence Number, V(S), which contains the value of the Frame Sequence Number, N(S), to be put in the Transfer Frame Header of the next Type-AD frame to be transmitted.

Precondition: the returned parameter is `transmitter-frame-sequence-number`.

```cpp
const FSP_AbsolutePriority* Get_VcPriorityList( int& size ) const;
```
Returns the priority specification for multiplexing on VCs if the multiplexing scheme is 'absolute priority'. The priority specification is an array of 'VC ID' - 'priority' pairs. If the multiplexing scheme is FIFO or 'polling vector', returns NULL.

**Precondition:** the returned parameter is vc-multiplexing-control.

**Arguments**

`size` set to the number of 'VC ID' - 'priority' pairs in the list

```cpp
const FSP_VcId* Get_VcPollingVector( int& size ) const;
```

Returns the polling vector for multiplexing on VCs if the multiplexing scheme is 'polling vector'. The polling vector is an array of VC IDs. If the multiplexing scheme is FIFO or 'absolute priority', returns NULL.

**Precondition:** the returned parameter is vc-multiplexing-control.

**Arguments**

`size` set to the number of identifiers in the list

```cpp
FSP_MuxScheme Get_VcMuxScheme() const;
```

Returns the multiplexing scheme in effect for VCs.

**Precondition:** the returned parameter is vc-multiplexing-scheme.

```cpp
FSP_VcId Get_VirtualChannel() const;
```

Returns the VC being used by this service instance.

**Precondition:** the returned parameter is virtual-channel.

```cpp
FSP_GetParameterDiagnostic Get_GetParameterDiagnostic() const;
```

Returns the diagnostic code.

**Precondition:** the result is negative, and the diagnostic type is set to 'specific'.

```cpp
void Set_RequestedParameter( FSP_ParameterName name );
```

Sets the parameter for which the provider shall report the value.

```cpp
void Set_ApIdList( const FSP_ApId* plist, int size );
```
Sets the returned parameter name to `apid-list` and copies the list supplied by the arguments to that parameter.

**Arguments**

`plist` array of application process identifiers (each APID must be in the range 0 to 2047)

`size` number of identifiers in the array

```c
void Put_ApIdList( FSP_ApId* plist, int size );
```

Sets the returned parameter name to `apid-list` and stores the list supplied by the arguments to that parameter.

**Arguments**

`plist` array of application process identifiers (each APID must be in the range 0 to 2047)

`size` number of identifiers in the array

```c
void Set_BlockingTimeout( unsigned long timeout );
```

Sets the returned parameter name to `blocking-timeout-period` and sets its value as defined by the argument.

```c
void Set_BlockingUsage( FSP_BlockingUsage usage );
```

Sets the returned parameter name to `blocking-usage` and sets its value as defined by the argument.

```c
void Set_DeliveryMode();
```

Sets the returned parameter name to `delivery-mode` and sets its value to ‘fwd online’.

```c
void Set_DirectiveInvocationEnabled( SLE_YesNo yesNo );
```

Specifies whether directive invocation is enabled for the service instance.

```c
void Set_DirectiveInvocationOnline( SLE_YesNo yesNo )
```

Specifies whether a service instance with directive invocation for the VC enabled is currently bound to the service provider.

```c
void Set_ExpectedDirectiveId( FSP_DirectiveId id );
```
Sets the returned parameter name to `expected-directive-id` and sets its value as defined by the argument.

```c
void Set_ExpectedEventInvocationId( FSP_EventInvocationId id );
```

Sets the returned parameter name to `expected-event-invocation-id` and sets its value as defined by the argument.

```c
void Set_ExpectedSlduId( FSP_PacketId id );
```

Sets the returned parameter name to `expected-sldu-identification` and sets its value as defined by the argument.

```c
void Set_FopSlidingWindow( unsigned long window );
```

Sets the returned parameter name to `fop-sliding-window` and sets its value as defined by the argument.

```c
void Set_FopState( FSP_FopState state );
```

Sets the returned parameter name to `fop-state` and sets its value as defined by the argument.

```c
void Set_MapList( const FSP_MapId* plist, int size );
```

Sets the returned parameter name to `map-list` and copies the list supplied by the arguments to that parameter.

**Arguments**

- `plist`: array of MAP IDs (each MAP ID must be in the range 0 to 63)
- `size`: number of identifiers in the array

```c
void Put_MapList( FSP_MapId* plist, int size );
```

Sets the returned parameter name to `map-list` and stores the list supplied by the arguments to that parameter.

**Arguments**

- `plist`: array of MAP IDs (each MAP ID must be in the range 0 to 63)
- `size`: number of identifiers in the array
void Set_MapPriorityList( const FSP_AbsolutePriority* priorities,  
           int size);

Sets the returned parameter name to map-multiplexing-control and copies the list supplied by the arguments to that parameter. Clears the map polling vector if that is set in the object. This method must be used when the multiplexing scheme is 'absolute priority'.

Arguments

plist array of MAP ID / Priority pairs as defined by FSP_AbsolutePriority  
(each MAP ID must be in the range 0 to 63 and each priority in the range 1 to 64)

size number of structures in the array

void Put_MapPriorityList( FSP_AbsolutePriority* priorities,  
           int size );

Sets the returned parameter name to map-multiplexing-control and stores the list supplied by the arguments to that parameter. Clears the map polling vector if that is set in the object. This method must be used when the multiplexing scheme is 'absolute priority'.

Arguments

plist array of MAP ID / Priority pairs as defined by FSP_AbsolutePriority  
(each MAP ID must be in the range 0 to 63 and each priority in the range 1 to 64)

size number of structures in the array

void Set_MapPollingVector( const FSP_MapId* pvec, int size );

Sets the returned parameter name to map-multiplexing-control and copies the list supplied by the arguments to that parameter. Clears the map priority list if that is set in the object. This method must be used when the multiplexing scheme is 'polling vector'.

Arguments

pvec array of MAP IDs (each MAP ID must be in the range 0 to 63)

size number of identifiers in the array

void Put_MapPollingVector( FSP_MapId* pvec, int size );

Sets the returned parameter name to map-multiplexing-control and stores the list supplied by the arguments to that parameter. Clears the map priority list if that is set in the object. This method must be used when the multiplexing scheme is 'polling vector'.

Arguments

pvec array of MAP IDs (each MAP ID must be in the range 0 to 63)

size number of identifiers in the array
Arguments

pvec array of MAP IDs (each MAP ID must be in the range 0 to 63)

size number of identifiers in the array

```c
void Set_MapMuxScheme( FSP_MuxScheme scheme );
```

Sets the returned parameter name to `map-multiplexing-scheme` and sets its value as defined by the argument.

```c
void Set_MaxFrameLength( unsigned long length );
```

Sets the returned parameter name to `maximum-frame-length` and sets its value as defined by the argument.

```c
void Set_MaxPacketLength( unsigned long length );
```

Sets the returned parameter name to `maximum-packet-length` and sets its value as defined by the argument.

```c
void Set_PermittedTransmissionMode( FSP_PermittedTransmissionMode mode );
```

Sets the returned parameter name to `permitted-transmission-mode` and sets its value as defined by the argument.

```c
void Set_ReportingCycle(unsigned long cycle );
```

Sets the returned parameter name to `reporting-cycle` and sets its value as defined by the argument.

```c
void Set_ReturnTimeoutPeriod( unsigned long period);
```

Sets the returned parameter name to `return-timeout-period` and sets its value as defined by the argument.

```c
void Set_SegmentHeaderPresent( SLE_YesNo yesNo );
```

Sets the returned parameter name to `segment-header` and sets its value as defined by the argument.

```c
void Set_TimeoutType( FSP_TimeoutType type );
```
Sets the returned parameter name to `timeout-type` and sets its value as defined by the argument.

```c
void Set_TimerInitial( unsigned long timeout );
```

Sets the returned parameter name to `timer-initial` and sets its value as defined by the argument.

**Arguments**

- `timeout` the initial value of the FOP countdown timer in microseconds

```c
void Set_TransmissionLimit( unsigned long limit );
```

Sets the returned parameter name to `transmission-limit` and sets its value as defined by the argument.

**Arguments**

- `limit` the maximum number a frame may be transmitted in the range 1 to 255.

```c
void Set_TransmitterFrameSequenceNumber( unsigned long number );
```

Sets the returned parameter name to `transmitter-frame-sequence-number` and sets its value as defined by the argument.

**Arguments**

- `number` the current value of the Transmitter Frame Sequence Number, V(S), which contains the value of the Frame Sequence Number, N(S), to be put in the Transfer Frame Header of the next Type-AD frame to be transmitted. The value must be in the range 0 to 255.

```c
void Set_VcPriorityList(const FSP_AbsolutePriority* priorities, int size);
```

Sets the returned parameter name to `vc-multiplexing-control` and copies the list supplied by the arguments to that parameter. Clears the VC polling vector if that is set in the object. This method must be used when the multiplexing scheme is 'absolute priority'.

**Arguments**

- `plist` array of VC ID / Priority pairs as defined by `FSP_AbsolutePriority` (each VC ID must be in the range 0 to 63 and each priority in the range 1 to 64)
- `size` number of structures in the array
void
Put_VcPriorityList( FSP_AbsolutePriority* priorities,
                   int size );

Sets the returned parameter name to `vc-multiplexing-control` and stores the list supplied by the arguments to that parameter. Clears the VC polling vector if that is set in the object. This method must be used when the multiplexing scheme is 'absolute priority'.

Arguments

plist array of VC ID / Priority pairs as defined by `FSP_AbsolutePriority`
(each VC ID must be in the range 0 to 63 and each priority in the range 1 to 64)

size number of structures in the array

void Set_VcPollingVector( const FSP_VcId* pvec, int size );

Sets the returned parameter name to `vc-multiplexing-control` and copies the list supplied by the arguments to that parameter. Clears the VC priority list if that is set in the object. This method must be used when the multiplexing scheme is 'polling vector'.

Arguments

pvec array of VC IDs (each VC ID must be in the range 0 to 63)

size number of identifiers in the array

void Put_VcPollingVector( FSP_VcId* pvec, int size );

Sets the returned parameter name to `vc-multiplexing-control` and stores the list supplied by the arguments to that parameter. Clears the VC priority list if that is set in the object. This method must be used when the multiplexing scheme is 'polling vector'.

Arguments

pvec array of VC IDs (each VC ID must be in the range 0 to 63)

size number of identifiers in the array

void Set_VcMuxScheme( FSP_MuxScheme scheme );

Sets the returned parameter name to `vc-multiplexing-scheme` and sets its value as defined by the argument.

void Set_VirtualChannel( FSP_VcId id );
Sets the returned parameter name to `virtual-channel` and sets its value as defined by the argument.

**Arguments**

`id`  
the value if the VC ID used by the service instance

```c
void
Set_GetParameterDiagnostic( FSP_GetParameterDiagnostic diagnostic );
```

Sets the result to ‘negative’, the diagnostic type to ‘specific’, and stores the value of the diagnostic code passed by the argument.

### Checking of Invocation Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>requested parameter</td>
<td>must not be 'invalid'</td>
</tr>
</tbody>
</table>

### Checking of Return Parameters

The interface ensures consistency between the returned parameter name and the parameter value, as the client cannot set the returned parameter name. The consistency checks defined below only need to be performed when the return is received by the service user. The method `VerifyReturnArguments()` might nevertheless be called on the provider side to check the permissible range of parameter arguments, unless the service element ensures that all values are within the range specified.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>returned parameter</td>
<td>must be the same as the requested parameter</td>

A3.6  FSP THROW EVENT OPERATION

Name IFSP_ThrowEvent
GUID  \{91DCEBA5-E896-11d4-9F17-00104B4F22C0\}
Inheritance: IUnknown – ISLE_Operation – ISLE_ConfirmedOperation
File IFSP_ThrowEvent.H

The interface provides access to the parameters of the confirmed operation FSP-THROW-EVENT.

Synopsis

```c
#include <FSP_Types.h>
#include <ISLE_ConfirmedOperation.H>

#define IID_IFSP_ThrowEvent_DEF { 0x91dceba5, 0xe896, 0x11d4, \
    { 0x9f, 0x17, 0x0, 0x10, 0x4b, 0x4f, 0x22, 0xc0 } }

interface IFSP_ThrowEvent : ISLE_ConfirmedOperation
{
    virtual unsigned short
        Get_EventId() const = 0;
    virtual const SLE_Octet*
        Get_EventQualifier( size_t& size ) const = 0;
    virtual FSP_EventInvocationId
        Get_EventInvocationId() const = 0;
    virtual FSP_EventInvocationId
        Get_ExpectedEventInvocationId() const = 0;
    virtual FSP_ThrowEventDiagnostic
        Get_ThrowEventDiagnostic() const = 0;
    virtual void
        Set_EventId( unsigned short id ) = 0;
    virtual void
        Set_EventQualifier( size_t size, const SLE_Octet* parg) = 0;
    virtual void
        Set_EventInvocationId( FSP_EventInvocationId id ) = 0;
    virtual void
        Set_ExpectedEventInvocationId( FSP_EventInvocationId id ) = 0;
    virtual void
        Set_ThrowEventDiagnostic (FSP_ThrowEventDiagnostic diagnostic) = 0;
};
```

Methods

```c

unsigned short Get_EventId() const;
```

Returns the identification of the event.

```c

const SLE_Octet* Get_EventQualifier( size_t& size ) const;
```

Returns the event qualifier as an array of octets or NULL if the parameter has not been set in the object.
Arguments

size set to the number of octets in the parameter on return

FSP_EventInvocationId Get_EventInvocationId() const;

Returns the invocation identifier of the event.

FSP_EventInvocationId Get_ExpectedEventInvocationId() const;

Returns the next expected invocation identifier of the event in the return.

FSP_ThrowEventDiagnostic Get_ThrowEventDiagnostic() const;

Returns the diagnostic code.

Precondition: the result is negative, and the diagnostic type is set to ‘specific’.

void Set_EventId( unsigned short id );

Sets the identifier of the event.

void Set_EventQualifier( size_t size, const SLE_Octet* parg);

Copies the octet string passed as argument to the parameter 'event qualifier'.

Arguments

parg pointer to the octet string

size the number of octets in the parameter

void Set_EventInvocationId( FSP_EventInvocationId id );

Sets the invocation identifier for the event in the invocation.

void Set_ExpectedEventInvocationId( FSP_EventInvocationId id );

Sets the next expected invocation identifier for the event in the return.

void Set_ThrowEventDiagnostic(FSP_ThrowEventDiagnostic diagnostic);

Sets the result to ‘negative’, the diagnostic type to ‘specific’, and stores the value of the diagnostic code passed by the argument.

    Set_ModifyMapPollingVector( FSP_MapId* pvec, int size ) = 0;
virtual void
    Set_InvokeDirectiveDiagnostic( FSP_InvokeDirectiveDiagnostic diag ) = 0;
};

Methods

FSP_DirectiveId Get_DirectiveId() const;
Returns the directive identification.

FSP_DirectiveId Get_ExpectedDirectiveId() const;
Returns the next directive identification expected by the provider.

FSP_Directive Get_Directive() const;
Returns the directive.

unsigned long Get_VR() const;
Returns the requested value of the receiver frame sequence number V(R).

Precondition: the directive is ‘initiate AD with set V(R)’.

unsigned long Get_VS() const;
Returns the requested value of the transmitter frame sequence number V(S).

Precondition: the directive is ‘set V(S)’.

unsigned long Get_FopSlidingWindowWidth() const;
Returns the requested width of the FOP sliding window.
Precondition: the directive is ‘set FOP sliding window width’.

```cpp
unsigned long GetTimerInitial() const;
```

Returns the requested timeout value in microseconds.

Precondition: the directive is ‘set T1 initial’.

```cpp
unsigned long Get_TransmissionLimit() const;
```

Returns the requested transmission limit.

Precondition: the directive is ‘set transmission limit’.

```cpp
FSP_DirectiveTimeoutType Get_TimeoutType() const;
```

Returns the requested timeout type

Precondition: the directive is ‘set timeout type’.

```cpp
FSP_AbsolutePriority* Get_Priority( int& size ) const;
```

 Returns an array with the requested priorities for the MAPs if the list was set in the object (the multiplexing scheme is 'absolute priority'). Otherwise returns a NULL pointer.

Precondition: the directive is ‘modify MAP multiplexing control’.

```cpp
FSP_MapId* Get_PollingVector( int& size ) const;
```

Returns the requested MAP polling vector if the vector was set in the object (the multiplexing scheme is 'polling vector'). Otherwise returns a NULL pointer.

Precondition: the directive is ‘modify MAP multiplexing control’.

```cpp
FSP_InvokeDirectiveDiagnostic Get_InvokeDirectiveDiagnostic() const;
```

Returns the diagnostics code.

Precondition: the result is negative, and the diagnostic type is set to ‘specific’.

```cpp
void Set_DirectiveId( FSP_DirectiveId id );
```

Sets the parameter 'directive identification' to the value passed as argument.

```cpp
void Set_ExpectedDirectiveId( FSP_DirectiveId id );
```
Sets the parameter 'expected directive identification' to the value passed as argument.

```c
void Set_InitiateADwithoutCLCW();
```
Sets the parameter 'directive' to 'initiate AD without CLCW'.

```c
void Set_InitiateADwithCLCW();
```
Sets the parameter 'directive' to 'initiate AD with CLCW'.

```c
void Set_InitiateADwithUnlock();
```
Sets the parameter 'directive' to 'initiate AD with Unlock'.

```c
void Set_InitiateADwithSetVR( unsigned long vr );
```
Sets the parameter 'directive' to 'initiate AD with Set V(R)' and stores the requested value of the receiver frame sequence number V(R).

**Arguments**

- `vr` the requested value of V(R) in the range 0 to 255

```c
void Set_TerminateAD();
```
Sets the parameter 'directive' to 'terminate AD'.

```c
void Set_ResumeAD();
```
Sets the parameter 'directive' to 'resume AD'.

```c
void Set_VS( unsigned long vs );
```
Sets the parameter 'directive' to 'set V(S)' and stores the requested value of the transmitter frame sequence number V(S).

**Arguments**

- `vs` the requested value of V(S) in the range 0 to 255

```c
void Set_FopSlidingWindow( unsigned long width );
```
Sets the parameter 'directive' to 'set FOP sliding window width' and stores the requested value of the window width.

**Arguments**
void Set_TimerInitial( unsigned long timeout );
Sets the parameter 'directive' to 'set T1 initial' and stores the requested value of the timeout.

Arguments

timeout the requested timeout value in microseconds

void Set_TransmissionLimit( unsigned long limit );
Sets the parameter 'directive' to 'set transmission limit' and stores the requested value of the limit.

Arguments

limit the requested transmission limit in the range 1 to 255

void Set_TimeoutType( FSP_DirectiveTimeoutType type );
Sets the parameter 'directive' to 'set timeout type' and stores the requested value passed as argument.

Arguments

type the requested timeout type

void Set_AbortVC();
Sets the parameter 'directive' to 'abort VC'.

void Set_ModifyMapPriorityList(FSP_AbsolutePriority* plist, int size);
Sets the parameter 'directive' to 'modify MAP multiplexing control' and stores the priority list passed as argument. This method must be used if the multiplexing scheme is 'absolute priority'. Clears the polling vector if it is set.

Arguments

plist the requested priority list as an array of 1 to 64 MAP ID / Priority pairs
size the number of elements in the array (1 - 64)

void Set_ModifyMapPollingVector( FSP_MapId* pvec, int size );
Sets the parameter 'directive' to 'modify MAP multiplexing control' and stores the polling vector passed as argument. This method must be used if the multiplexing scheme is 'polling vector'. Clears the priority list if it is set.

**Arguments**

<table>
<thead>
<tr>
<th>pvec</th>
<th>the requested polling vector as an array of 1 to 192 MAP IDs</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>the number of elements in the array (1 - 192)</td>
</tr>
</tbody>
</table>

```cpp
void
Set_InvokeDirectiveDiagnostic(FSP_InvokeDirectiveDiagnostic diag);
```

Sets the result to ‘negative’, the diagnostic type to ‘specific’, and stores the value of the diagnostic code passed by the argument.

**Initial Values of Operation Parameters after Creation**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Created directly</th>
<th>Created by Service Instance</th>

</tr>
</tbody>
</table>

**Checking of Invocation Parameters**

The interface ensures consistency between the directive and the directive parameters, as the client cannot set the directive directly. The consistency checks defined below only need to be performed when the invocation is received by the service provider. The method
VerifyInvocationArguments() should nevertheless be called on the user side to check the permissible range of parameter arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>directive</td>
<td>Must not be 'invalid'</td>
</tr>
<tr>
<td>V(R)</td>
<td>If the directive is 'initiate AD with set V(R)' must be a value in the range 0 to 255.</td>

A4 FSP SERVICE INSTANCE INTERFACES

A4.1 SERVICE INSTANCE CONFIGURATION

Name IFSP_SIAdmin
GUID {91DCEBA6-E896-11d4-9F17-00104B4F22C0}
Inheritance: IUnknown
File IFSP_SIAdmin.H

The interface provides write and read access to the FSP-specific service instance configuration parameters. All configuration parameters must be set as part of service instance configuration. When the method ConfigCompleted() is called on the interface ISLE_SIAdmin, the service element checks that all parameters have been set and returns an error when the configuration is not complete.

FSP specific configuration parameters are not processed or modified by the API. They are only used for the following purposes:

– to inform the service user via the GET-PARAMETER operation,
– to initialise parameters of the status report; or
– for checking of operation parameters.

FSP configuration parameters can be modified at any time. The API always uses the last value set in GET-PARAMETER returns. Parameters used for initialization of the status report must not be set after invocation of ConfigCompleted(). The effect of invoking these methods at a later stage is undefined.

As a convenience for the application, the interface provides read access to the configuration parameters, except for parameters used to initialise the status report. If retrieval methods are called before configuration, the value returned is undefined.

It is noted that service management might constrain the range of parameters that can be modified after configuration. The API does not enforce these constraints.

In addition to the FSP configuration parameters accessible via this interface, the FOP parameters controlled via the interface IFSP_FOPMonitor must be initialized before calling ConfigCompleted().

Synopsis

Methods

void Set_MaximumFrameLength( unsigned int length );
Sets the mission maximum TC transfer frame length in octets.

Arguments

length  a number in the range 12 to 1026 octets

void Set_MaximumPacketLength( unsigned int length );
Sets the mission maximum telecommand packet length in octets.

Arguments

length  a number in the range 7 to 65542 octets

void Set_VcMuxScheme( FSP_MuxScheme scheme );
Sets the VC multiplexing scheme in effect: ('FIFO', 'absolute priority', 'polling vector').

void Set_VcPriorityList( const FSP_AbsolutePriority* priorities,
                         int size );
Sets the priority list for the VC multiplexing scheme 'absolute priority’. Must not be set if the
VC multiplexing scheme is 'FIFO' or 'polling vector'.

Arguments

priorities  an array of VC ID priority pairs as defined by the type
            FSP_AbsolutePriority.
size  the number of elements in the list

void Set_VcPollingVector( const FSP_VcId* pvec, int size );
Sets the polling vector for the VC multiplexing scheme 'polling vector’. Must not be set if the
VC multiplexing scheme is 'FIFO' or 'absolute priority’.

Arguments

pvec  an array of VC IDs in the sequence the VCs are polled
size  the number of elements in the vector
void Set_BlockingTimeout( unsigned long timeout );

Sets the period from inserting the first packet into the TC frame data unit until this unit is passed to the FOP regardless of the number of packets contained. Shall not be set when blocking usage is set to 'permitted'.

Arguments

timeout timeout period in microseconds (TBC)

void Set_BlockingUsage( FSP_BlockingUsage usage );

Defines whether packet blocking is permitted on the VC.

void Set_DirectiveInvocationEnabled( SLE_YesNo yesNo );

Defines whether the service instance being configured is allowed to invoke directives. The argument shall be set to 'yes' if this service instance is authorized to invoke the FSP-INVOKE-DIRECTIVE operation, and to 'no' otherwise.

void Set_SegmentHeaderPresent( SLE_YesNo yesNo );

Specifies whether a segment header is present ('yes') or absent ('no') in the TC transfer frames.

void Set_ApIdList( const FSP_ApId* plist, int size );

Specifies the list of APIDs the given service instance is authorized to access.

Arguments

plist array of APIDs, each APID is in the range 0 to 2047

size number of APIDs in the array (1 to 2048)

void Set_MapList( const FSP_MapId* plist, int size );

Specifies the list of MAPs permitted to be used by the given service instance if MAPs are used. Must not be set when MAPs are not used.

void Set_VirtualChannel( FSP_VcId id );

 Specifies the virtual channel used by this service instance.

void Set_PermittedTransmissionMode( FSP_PermittedTransmissionMode mode );
Specifies the transmission mode permitted to be used by the given service instance.

```cpp
void Set_MaximumBufferSize( FSP_BufferSize size );
```

Specifies the maximum packet buffer size in units of octets. This value is used to initialize the status parameter packet buffer available.

**Precondition**: ISLE_SIAdmin::ConfigCompleted() was not called yet.

```cpp
void Set_InitialProductionStatus( FSP_ProductionStatus status );
```

Sets the production status at the time of service instance configuration. The value is used to initialize the status parameter production status. The current value of the production status can be retrieved via the interface IFSP_SIUpdate.

**Precondition**: ISLE_SIAdmin::ConfigCompleted() was not called yet.

```cpp
void Set_InitialDirectiveInvocationOnline( SLE_YesNo yesNo );
```

Specifies whether a service instance with directive invocation capability is connected at the time of configuration. This method only needs to be called when directive invocation is not enabled for the service instance. If directive invocation is enabled, the method invocation is ignored. The current value of the parameter can be retrieved via the interface IFSP_SIUpdate.

**Precondition**: ISLE_SIAdmin::ConfigCompleted() was not called yet.

```cpp
unsigned int Get_MaximumFrameLength() const;
```

Returns the mission maximum TC transfer frame length in octets.

```cpp
unsigned int Get_MaximumPacketLength() const;
```

Returns the maximum packet length.

```cpp
FSP_MuxScheme Get_VcMuxScheme() const;
```

Returns the VC multiplexing scheme in effect.

```cpp
const FSP_AbsolutePriority* Get_VcPriorityList( int& size ) const;
```

Returns the priority list as a vector of VC ID/priority pairs if the VC multiplexing scheme is 'absolute priority'. If the multiplexing scheme is 'FIFO' or 'polling vector', returns NULL.

```cpp
const FSP_VcId* Get_VcPollingVector( int& size ) const;
```
Returns the polling vector as an array of VCIDs if the VC multiplexing scheme is 'polling vector'. If the multiplexing scheme is 'FIFO' or 'absolute priority', returns NULL.

unsigned long Get_BlockingTimeout() const;

Returns the blocking timeout period.

**Precondition:** Get_BlockingUsage() returns 'permitted'.

**FSP_BlockingUsage** Get_BlockingUsage() const;

Returns whether blocking of packets is permitted.

**SLE_YesNo** Get_DirectiveInvocationEnabled() const;

Returns 'yes' if the service instance is allowed to invoke the FSP-INVOKE-DIRECTIVE operation and 'no' otherwise.

**SLE_YesNo** Get_SegmentHeaderPresent() const;

Returns 'yes' if a segment header is present in the TC transfer frames, and 'no' otherwise.

const **FSP_ApId*** Get_ApIdList( int& size ) const;

Returns the list of APIDs the service instance is authorized to access.

const **FSP_MapId*** Get_MapList( int& size ) const;

Returns the list of MAPs the service instance is authorized to access.

**FSP_VcId** Get_VirtualChannel() const;

Returns the virtual channel used by the service instance.

**FSP_PermittedTransmissionMode** Get_PermittedTransmissionMode() const;

Returns the transmission mode the service instance is authorized to use.

**FSP_BufferSize** Get_MaximumBufferSize() const;

Returns the maximum packet buffer size.
A4.2  FOP MONITORING AND CONTROL

Name  IFSP_FOPMonitor
GUID  {D9E3A601-641A-11d5-9CF0-0004761E8CFB}
Inheritance:  IUnknown
File  IFSP_FOPMonitor.H

The interface provides access to the FSP parameters related to the FOP machine of the VC on which the service instance operates including
– parameters controlling operation the FOP machine; and
– parameters monitoring the FOP state and variables.

The API service instance uses these parameters only to respond to GET-PARAMETER invocations. All parameters must be set when the service instance is being configured before the method ConfigCompleted() is called on the interface ISLE_SIAdmin. The service instance verifies completeness and consistency of the parameters within the method ConfigCompleted().

During the lifetime of the service instance, FOP related parameters must be updated whenever they change. Changes might occur due to directives invoked by a service user on the same or on a different service instance, due to events detected by the FOP machine, or due to management action. In order to ensure that the service instance always reports the correct parameter value, updates must be reported independent of the service instance state.

The parameters 'map-multiplexing-scheme' and 'map-multiplexing-control' are included in this interface because 'map-multiplexing-control' can be modified by the service user via a directive.

Synopsis
#include <FSP_Types.h>

virtual const FSP_MapId*
    Get_MapPollingVector( int& size ) const = 0;

virtual FSP_MuxScheme
    Get_MapMuxScheme() const = 0;
};

Methods

void Set_FopSlidingWindow( unsigned long window );

Sets the FOP sliding window width, i.e. the number of frames that can be transmitted on the
given VC before an acknowledgement is required.

Arguments

window     a number in the range 1 to 255

void Set_TimeoutType( FSP_TimeoutType type );

Specifies the FOP behavior in case of a timeout (‘Alert’ or ‘AD service suspension’).

void Set_TimerInitial( unsigned long timeout );

Specifies the initial value for countdown timer when an AD or BC frame is transmitted.

Arguments

timeout    timer value in microseconds

void Set_TransmissionLimit( unsigned long limit );
Specifies the maximum number of times the first frame on the Sent Queue may be transmitted.

```c
void Set_TransmitterFrameSequenceNumber( unsigned long number );
```

Sets the current value of the FOP Transmitter Frame Sequence Number, V(S), which contains the value of the Frame Sequence Number, N(S), to be put in the Transfer Frame Header of the next Type AD frame to be transmitted. The parameter shall be updated, whenever the transmission mode capability changes (i.e. when the sequence controlled service is suspended, terminated, or started).

**Arguments**

- `number` V(S) value in the range 0 to 255

```c
void Set_FopState( FSP_FopState state );
```

Sets the current value of the FOP state. The parameter shall be updated for every changed of the FOP state.

```c
void Set_MapPriorityList( const FSP_AbsolutePriority* priorities, int size );
```

Sets the priority list for the MAP multiplexing scheme 'absolute priority'. Must not be set if the MAP multiplexing scheme is 'FIFO' or 'polling vector'.

**Arguments**

- `priorities` an array of MAP ID priority pairs as defined by the type `FSP_AbsolutePriority`
- `size` the number of elements in the list

```c
void Set_MapPollingVector( const FSP_MapId* pvec, int size );
```

Sets the polling vector for the MAP multiplexing scheme 'polling vector'. Must not be set if the MAP multiplexing scheme is 'FIFO' or 'absolute priority'.

**Arguments**

- `pvec` an array of MAP IDs in the sequence the MAPs are polled
- `size` the number of elements in the vector

```c
void Set_MapMuxScheme( FSP_MuxScheme scheme );
```
Sets the MAP multiplexing scheme in effect: (‘FIFO’, ‘absolute priority’, ‘polling vector’).

```
unsigned long Get_FopSlidingWindow() const;
```

Returns the FOP sliding window width.

```
FSP_TimeoutType Get_TimeoutType() const;
```

Returns the current setting of the timeout type (‘Alert’ or ‘AD service suspension’).

```
unsigned long Get_TimerInitial() const;
```

Returns the initial value of the FOP countdown timer in microseconds.

```
unsigned long Get_TransmissionLimit() const;
```

Returns the FOP (re-)transmission limit.

```
unsigned long Get_TransmitterFrameSequenceNumber() const;
```

Returns the current value of the FOP variable V(S) – this value is only updated when the transmission mode capability changes.

```
FSP_FopState Get_FopState() const;
```

Returns the current value of the FOP state.

```
const FSP_AbsolutePriority* Get_MapPriorityList( int& size ) const;
```

Returns the priority list as a vector of MAP ID/priority pairs if the MAP multiplexing scheme is 'absolute priority'. If the multiplexing scheme is 'FIFO' or 'polling vector', returns NULL.

```
const FSP_MapId* Get_MapPollingVector( int& size ) const;
```

Returns the polling vector as an array of MAP IDs if the MAP multiplexing scheme is 'polling vector'. If the multiplexing scheme is 'FIFO' or 'absolute priority', returns NULL.

```
FSP_MuxScheme Get_MapMuxScheme() const;
```

Returns the MAP multiplexing scheme in effect.
A4.3 UPDATE OF SERVICE INSTANCE PARAMETERS

Name IFSP_SIUpdate
GUID {91DCEBA7-E896-11d4-9F17-00104B4F22C0}
Inheritance: IUnknown
File IFSP_SIUpdate.H

The interface provides methods to update parameters that shall be reported to the service user via the operations FSP-STATUS-REPORT, FSP-ASYNC-NOTIFY, and FSP-GET-PARAMETER. In order to keep this information up to date the appropriate methods of this interface must be called whenever certain events occur (see the specification in 3.1). If these events must be reported to the FSP service user via a notification, the API can be requested to send the notification. Alternatively the application can generate and send the notification itself.

The methods of this interface must always be called when one of the relevant events occurs, independent of the state of the service instance. Notifications to the user will only be sent, if the service instance state is either ‘ready’ or ‘active’. Failure to inform the API of an event can result in incorrect and inconsistent parameters in the status report.

Because of performance considerations, methods processing nominal events perform no plausibility checks, but completely rely on the application to provide correct and consistent arguments.

The interface provides read access to the parameters set via this interface and to parameters accumulated or derived by the API according to the specifications in 3.1.4. The API sets the parameters to the initial values specified at the end of this section when the service instance is configured. Parameter values retrieved before configuration are undefined.

Synopsis

```c
#include <FSP_Types.h>
#include <SLE_SCM.H>

virtual FSP_EventInvocationId
    Get_ExpectedEventInvocationId() const = 0;
};

Methods

void
PacketStarted(FSP_PacketId packetId,
                FSP_TransmissionMode mode,
                const ISLE_Time& startTime,
                FSP_BufferSize bufferAvailable
                bool notify );

The method shall be called when processing of a packet has been started, i.e. the packet has
been extracted from the packets queue and forwarded to the segments queue. It performs the
following actions:

a) If the value of mode is 'sequence controlled', increments the number of AD packets
   processed otherwise increments the number of BD packets processed.

b) Stores the value of the argument(packetId to the parameter packet-
   identification-last-processed.

c) Copies the startTime to the parameter production-start-time.

d) Sets the parameter packet-status to 'production started'.

e) Sets the parameter packet-buffer-available to the value passed by the
   argument bufferAvailable.

f) If the argument notify is true:

   1) Creates an empty packet identification list and inserts the argument packetId
      into that parameter.

   2) Sends the notification ‘packet processing started’ to the service user provided
      sending of notifications is allowed according to the state tables in reference [7].

Preconditions

The client must ensure the following preconditions since they are not checked by the
implementation:

a) The production status must be 'operational'.
b) If the transmission mode is 'sequence controlled' the production status must be 'operational AD and BD'.

c) The argument notify must only be set to TRUE if the service user has requested a 'processing started' notification for the packet.

Arguments

packetId the identification of the packet for which processing started
mode the transmission mode ('sequence controlled' or 'expedited') of the packet
startTime the time at which processing of the packet started
bufferAvailable the amount of packet buffer currently available
notify if true a notification shall be sent to the service user

void PacketRadiated( FSP_PacketId packetId,  
                    const ISLE_Time& radiationTime,  
                    FSP_TransmissionMode mode,           
                    bool notify );

The method shall be called when a packet has been completely radiated. If segmentation is used, this implies that the last segment of the packet was radiated. The method performs the following actions:

a) If the value of mode is 'sequence controlled', increments the number of AD packets radiated otherwise increments the number of BD packets radiated.

b) If the value of mode is 'expedited', sets the parameter packet identification last OK to the value of the argument packetId and copies the radiationTime to the parameter production-stop-time.

c) If the argument packetId equals the parameter packet-identification-last-processed, sets the parameter packet status to 'packet radiated'.

d) If the argument notify is true:

1) Creates an empty packet identification list and inserts the argument packetId into that parameter.

2) Sends the notification ‘packet radiated’ to the service user provided sending of notifications is allowed according to the state tables in reference [7].

Preconditions
The client must ensure the following preconditions since they are not checked by the implementation:

a) The production status must be ‘operational’.

b) If the transmission mode is 'sequence controlled' the production status must be 'operational AD and BD'

c) The argument notify must only be set to TRUE if the service user has requested a ‘radiated’ notification for the packet.

Arguments

- **packetId**: the identification of the packet that was radiated
- **mode**: the transmission mode ('sequence controlled' or 'expedited') of the packet
- **radiationTime**: the time at which radiation completed
- **notify**: if true a notification shall be sent to the service user

```cpp
void PacketAcknowledged( FSP_PacketId packetId,
                         const ISLE_Time& ackTime,
                         bool notify );
```

The method shall be called when all components of a packet were acknowledged by the space element via the associated stream of CLCWs. It performs the following actions:

a) Increments the parameter number of packets acknowledged.

b) Sets the parameter packet identification last OK to the value of the argument packetId.

c) Copies ackTime to the parameter 'production stop time'.

d) If the argument packetId equals the parameter packet identification last processed, sets the parameter packet status to 'packet acknowledged'.

e) If the argument notify is true

1) Creates an empty packet identification list and inserts the argument packetId into that parameter.

2) Sends the notification ‘packet acknowledged’ to the service user provided sending of notifications is allowed according to the state tables in reference [7].

Preconditions
The argument notify must only be set to TRUE if the service user has requested an ‘acknowledged’ notification for the packet.

**Arguments**

- **packetId** the identification of the packet that was acknowledged
- **ackTime** the time at which the last component of the packet was acknowledged
- **notify** if true a notification shall be sent to the service user

```c
void BufferEmpty( bool notify );
```

The method shall be called when the packet buffer becomes empty because all packets were processed. It shall not be called when the packet buffer is cleared due to one of the events for which reference [5] requires discarding of buffered packets.

The method performs the following actions:

a) Sets the parameter packet buffer available to the maximum buffer size set by configuration of the service instance.

b) If the argument notify is true, sends the notification ‘buffer empty' to the service user provided sending of notifications is allowed according to the state tables in reference [7].

**Arguments**

- **notify** if true a notification shall be sent to the service user

```c
HRESULT PacketNotStarted( FSP_PacketId packetId,
                          FSP_TransmissionMode mode,
                          const ISLE_Time& startTime,
                          FSP_Failure reason,
                          const FSP_PacketId* affectedPackets,
                          int numAffected,
                          FSP_BufferSize bufferAvailable,
                          bool notify );
```

The method shall be called when processing of a packet could not be started because:

- the latest production start time was expired;
- the production status was 'interrupted'; or
- the required transmission mode was not available.

It performs the following actions:
a) If the value of mode is 'sequence controlled', increments the number of AD packets processed otherwise increments the number of BD packets processed.

b) Sets the parameter packet identification last processed to the value of the argument packetId.

c) Copies the startTime to the parameter production start time.

d) Sets the parameter packet status to 'expired', 'interrupted', or 'unsupported transmission mode' according to the value of the argument reason.

e) Sets the parameter packet buffer available to the value passed by the argument bufferAvailable.

f) If the argument notify is true and sending of notifications is allowed according to the state tables in reference [7].

   1) Creates an empty packet identification list and inserts the argument packetId and all identifiers in the argument affectedPackets into that parameter.

   2) If reason is 'expired', sends the notification 'sldu expired' to the service user.

   3) If reason is 'interrupted', sends the notification 'production interrupted' to the service user.

   4) If reason is 'transmission mode mismatch', sends the notification 'transmission mode mismatch' to the service user.

Arguments

packetId the identification of the packet for which processing could not be started

mode the transmission mode ('sequence controlled' or 'expedited') of the packet

startTime the time at which processing of the packet was attempted

reason the reason why processing could not be started

affectedPackets an array containing the identifiers of all packets (excluding the identifier passed by packetId) that were or will be discarded due to the problem detected; if packetId is the only affected packet, a NULL pointer shall be supplied and the argument numAffected shall be set to zero.

numAffected the number of packet identifiers in the array affectedPackets

bufferAvailable the amount of packet buffer currently available

notify if true a notification shall be sent to the service user

Result codes
S_OK  the updates have been made and the notification was sent if requested.

SLE_E_INCONSISTENT  the arguments supplied are inconsistent (see NOTE) – updates have not been performed and a notification has not been sent.

SLE_E_STATE  the service instance state is ‘unbound’ (it might have aborted) – updates have been performed but the requested notification could not be sent.

NOTE  – The result code SLE_E_INCONSISTENT indicates one of the following problems:

   a) reason is 'interrupted' but the production status is not 'interrupted' or 'halted'; or

   b) reason is 'transmission mode mismatch' but mode is 'expedited'.

HRESULT

HRESULT ProductionStatusChange( FSP_ProductionStatus newStatus,
                                  const FSP_PacketId* affectedPackets,
                                  int numAffected,
                                  FSP_PopAlert fopAlert,
                                  FSP_BufferSize bufferAvailable,
                                  bool notify );

The method shall be called whenever the production status changes, including changes of the operational sub-states. It performs the following actions:

   a) Sets the parameter production status to newStatus.

   b) If the argument affectedPackets is not NULL and contains the identifier stored in the parameter packet identification last processed, sets the parameter packet status to

      – 'interrupted' if the new production status is 'halted' or 'interrupted'; or

      – 'unsupported transmission mode' if the new production status is 'operational'.

   c) Sets the parameter packet buffer available to the value passed by the argument bufferAvailable.

   d) If the argument notify is true and sending of notifications is allowed according to the state tables in reference [7].

      1) If the argument affectedPackets is not NULL and not empty, creates an empty packet identification list and copies all identifiers in the argument affectedPackets to that parameter.

      2) If the production status changed to 'halted' sends the notification 'production halted' to the service user.
3) If the production status changed to 'interrupted' and the argument `affectedPackets` is not NULL and not empty, sends the notification 'production interrupted' to the service user.

4) If the production status changed from 'operational AD and BD' to 'interrupted' and the argument `affectedPackets` is NULL or empty, sends the notification 'transmission mode capability change' to the service user.

5) If the new production status is operational and a different production status value was previously reported to the user or no status was reported at all, sends the notification 'production operational' to the service user.

6) If the new production status is 'operational BD' or 'operational AD suspended' and the previous value of the production status was 'operational AD and BD' or if the new production status is 'operational AD and BD' and the previous value of the production status was 'operational BD' or 'operational AD suspended', sends the notification 'transmission mode capability change' to the service user.

7) If the new production status is 'operational BD' or 'operational AD suspended' and the argument `affectedPackets` is not NULL, sends the notification 'packet transmission mode mismatch' in addition to the notification 'transmission mode capability change'.

Arguments

`newStatus` the new value of the production status

`affectedPackets` an array containing the identifiers of all packets that was or will be discarded due to the change of the production status; if no packets are affected by the change of the production status, a NULL pointer shall be supplied and the argument `numAffected` shall be set to zero.

`numAffected` the number of packet identifiers in the array `affectedPackets`

`fopAlert` the FOP Alert that caused the transmission mode capability change, if applicable. If the transmission mode capability did not change, the API ignores this argument.

`bufferAvailable` the amount of packet buffer currently available

`notify` if true a notification shall be sent to the service user

Result codes

`S_OK` the updates were made and a notification was sent if required and requested

`SLE_S_IGNORED` the production status has not changed; the request was ignored.
SLE_E_INCONSISTENT  the arguments supplied are inconsistent (see NOTE) – updates have not been performed and a notification has not been sent

SLE_E_SEQUENCE  there is no valid transition between the old and the new production status – this is only a warning, updates were made and notifications were sent if requested

SLE_E_STATE  the service instance state is ‘unbound’ (it might have aborted) – updates have been performed but the requested notification could not be sent

NOTES

1  If the production status did not change or the value of the new production status is 'configured' no notification is sent.

2  Valid transitions of the production status are defined in reference [5].

3  The result code SLE_E_INCONSISTENT indicates one of the following problems:
   a)  The argument affectedPackets is not NULL although:
      –  the new production status is either 'configured' or 'operational AD and BD';
      –  the old production status was not 'operational'; or
      –  the production status changed from 'operational AD suspended' to 'operational BD'.
   b)  The new production status is 'interrupted' or 'halted' and the packet status is 'production started' but the argument affectedPackets is NULL or the packet identification last processed in not contained in the list.
   c)  The old production status was 'configured' or 'interrupted' and the new status is 'operational' but the sub-state is not 'BD'.

4  If the production status change was caused by the directive 'abort VC' the method VCAborted() must be called instead of ProductionStatusChange().

HRESULT

VCAborted( const FSP_PacketId* affectedPackets,
           int numAffected,
           FSP_BufferSize bufferAvailable,
           bool notify );

The method shall be called following successful execution of the directive 'abort VC'. It performs the following actions:

a)  Sets the parameter production status to 'operational BD'
b) If the identifier in the parameter packet identification last processed is included in the argument `affectedPackets` sets the parameter packet status to 'interrupted'.

c) Sets the parameter packet buffer available to the value passed by the argument `bufferAvailable`.

d) If the argument `notify` is true:

1) If `affectedPackets` is not NULL and not empty creates an empty packet identification list and copies all identifiers in the argument `affectedPackets` to that parameter.

2) Sends the notification 'VC aborted' to the service user provided sending of notifications is allowed according to the state tables in reference [7].

The directive 'VC aborted' will generally cause a change of the production status to 'operational BD'. This change is handled by the method VCAborted. Therefore, the method ProductionStatusChange() must not be called in this case.

Arguments

- `affectedPackets` an array containing the identifiers of all packets that were or will be discarded; if no packets are affected by the directive 'abort VC', a NULL pointer shall be supplied and the argument `numAffected` shall be set to zero
- `numAffected` the number of packet identifiers in the array `affectedPackets`
- `bufferAvailable` the amount of packet buffer currently available
- `notify` if true a notification shall be sent to the service user

Result codes

- `S_OK` the updates were made and the notification was sent if requested.
- `SLE_E_INCONSISTENT` the packet status is 'production started' but the argument `bufferAvailable` is NULL or the packet identification last processed is not contained in the list - updates have not been performed and a notification has not been sent.
- `SLE_E_SEQUENCE` The value of the production status was not 'operational' when the method was called – updates have not been performed and a notification has not been sent.
- `SLE_E_STATE` the service instance state is 'unbound' (it might have aborted) – updates have been performed but the requested notification could not be sent.

```c
HRESULT NoDirectiveCapability( bool notify );
```
The method is called when the service instance that has the directive invocation capability for
the VC is unbound following an UNBIND operation, a PEER-ABORT operation, or a
protocol abort event. It performs the following actions if directive invocation is not enabled
for the service instance:

a) Sets the parameter 'directive invocation online' to 'no'.

b) If the argument notify is true sends the notification 'no invoke directive capability on
this VC' to the service user provided sending of notifications is allowed according to
the state tables in reference [7].

Arguments

notify if true a notification shall be sent to the service user.

Result codes

S_OK the notification was sent if requested.

SLE_S_IGNORED directive invocation is enabled for this service instance; the request has
been ignored.

SLE_E_STATE the service instance state is 'unbound' (it might have aborted); the
requested notification could not be sent.

HRESULT DirectiveCapabilityOnline( bool notify );

The method is called when a service instance that has the directive invocation capability for
the VC has successfully bound to the service provider. It performs the following actions if
directive invocation is not enabled for the service instance:

a) Sets the parameter 'directive invocation online' to 'yes'.

b) If the argument notify is true sends the notification 'invoke directive capability on this
VC established' to the service user provided sending of notifications is allowed according to
the state tables in reference [7].

Arguments

notify if true a notification shall be sent to the service user.

Result codes

S_OK the notification was sent if requested.

SLE_S_IGNORED directive invocation is enabled for this service instance; the request has
been ignored.
the service instance state is ‘unbound’ (it might have aborted); the requested notification could not be sent.

**HRESULT**

`DirectiveCompleted( FSP_DirectiveId directiveId, SLE_Result result, FSP_FopAlert fopAlert, bool notify );`

The method should be called when execution of a directive was completed successfully or failed. If the value of the argument result is 'positive result' the method generates and transmits the notification 'positive confirm response to directive'. If the result is 'negative result', it generates and transmits the notification 'negative confirm response to directive'.

**Arguments**

directiveId  the directive identification as contained in the FSP-INVOKE-DIRECTIVE invocation

result  the result of directive execution ('positive result' or 'negative result')

fopAlert  in case of a negative result, the FOP alert indicating why the directive failed; if result is 'positive result', the method ignores this argument

notify  if true a notification shall be sent to the service user; because sending the notification is the only action of the method this argument is not really needed – it is provided for consistency with other methods in this interface.

**Result codes**

**S_OK**  the notification was sent if requested.

**SLE_E_STATE**  the service instance state is ‘unbound’ (it might have aborted); the requested notification could not be sent.

**HRESULT**

`EventProcCompleted( FSP_EventInvocationId eventId, FSP_EventResult result, bool notify );`

The method should be called when processing of an event requested by an accepted FSP-THROW-EVENT operation completed. Depending on the value of the argument result, the method generates and transmits one of the notifications 'action list completed', 'action list not completed', or 'event condition evaluated to false'.

**Arguments**
eventId  
the event invocation identifier as contained in the FSP-THROW-EVENT

result  
the result of event processing (‘completed’, 'not completed', or 'condition false')

notify  
if true a notification shall be sent to the service user; because sending the

notification is the only action of the method this argument is not really needed – it is provided
for consistency with other methods in this interface.

Result codes

S_OK  
the notification was sent if requested.

SLE_E_STATE  
the service instance state is ‘unbound’ (it might have aborted); the
requested notification could not be sent.

FSP_ProductionStatus Get_ProductionStatus() const;

Retruns the current value of the production status maintained by the service instance.

SLE_YesNo Get_DirectiveInvocationOnline() const;

Returns yes when a service instance with directive invocation capability enabled is connected
and 'no' otherwise.

FSP_BufferSize Get_PacketBufferAvailable() const;

Returns the current value of the parameter packet buffer available maintained by the service
instance.

unsigned long Get_NumberOfADPacketsReceived() const;

Returns the accumulated number of AD packets received as derived from FSP-TRANSFERN-
DATA returns.

unsigned long Get_NumberOfBDPacketsReceived() const;

Returns the accumulated number of BD packets received as derived from FSP-TRANSFER-
DATA returns.

unsigned long Get_NumberOfADPacketsProcessed() const;

Returns the accumulated number of AD packets processed including those for which
processing was started but could not be completed and those for which start of processing
was attempted.
unsigned long Get_NumberOfBDPacketsProcessed() const;

Returns the accumulated number of BD packets processed including those for which processing was started but could not be completed and those for which start of processing was attempted.

unsigned long Get_NumberOfADPacketsRadiated() const;

Returns the accumulated number of AD packets that were completely radiated.

unsigned long Get_NumberOfBDPacketsRadiated() const;

Returns the accumulated number of BD packets that were radiated.

unsigned long Get_NumberOfPacketsAcknowledged() const;

Returns the accumulated number of AD packets, for which processing was completed.

FSP_PacketId Get_PacketLastProcessed() const;

Returns the current value of the parameter packet identification last processed.

Precondition: either Get_NumberOfADPacketsProcessed() or Get_NumberOfBDPacketsProcessed() returns a non-zero number.

const ISLE_Time* Get_ProductionStartTime() const;

Returns the time at which processing of the packet identified by the parameter packet identification last processed started or was attempted. If no packets were processed yet, returns a NULL pointer.

FSP_PacketStatus Get_PacketStatus() const;

Returns the status of the packet identified by the parameter packet identification last processed. If no packets were processed yet, returns 'invalid'.

FSP_PacketId Get_PacketLastOk() const;

Returns the current value of the parameter packet identification last OK.

Precondition: either Get_NumberOfADPacketsAcknowledged() or Get_NumberOfBDPacketsRadiated() returns a non-zero number.

const ISLE_Time* Get_ProductionStopTime() const;
Returns the time at which the packet identified by packet identification last OK completed processing. If no packets completed processing yet, returns a NULL pointer.

FSP_PacketId Get_ExpectedPacketId() const;

Returns the packet identification expected next as derived from FSP-START and FSP-TRANSFER-DATA operations.

FSP_DirectiveId Get_ExpectedDirectiveInvocationId() const;

Returns the directive invocation identifier expected next as derived from FSP-INVOKE-DIRECTIVE operations.

FSP_EventInvocationId Get_ExpectedEventInvocationId() const;

Returns the event invocation identifier expected next as derived from FSP-THROW-EVENT operations.
